1 Data

1.1 Data sources

Empirical fertility data would ideally be collected and published as counts of live births by age of the mother through a system of civil registration and vital statistics (CRVS). However, not all countries produce or make available vital registration (VR) data that are reliable with national coverage and a high level of completeness. For those countries with lacking or deficient VR data, empirical fertility data can be complemented using estimates coming from household surveys that collect information on the complete childbearing history of the women interviewed. Such surveys are, for example, the Demographic and Health Survey (DHS), the Multiple Indicators Cluster Survey (MICS), and other international survey programs¹. Other countries, instead, rely on their own national demographic surveys or sample vital registration systems. Many population censuses also collect fertility data by asking women about the number of children ever born and about the births that occurred in the 12 (or 24) months prior to the census date.

The estimates of age-specific fertility rates for girls aged 10–14 and 15–19 presented in this paper are based on a set of empirical data points, which have been collected and stored in the internal database of the United Nations Population Division (DemoData SQL)². From the data available in the database, we selected those series that met the highest standards. In particular, we included only VR data for location-years for which birth registration completeness was higher than 60% [6]. In case of more than one series of estimates or VR that were available in a specific country-year, we kept only one series of estimates and one series of VR to avoid duplication.

1.2 Data availability

This study only reports the model estimates of age-specific fertility rates for mothers aged 10–14 and 15–19 among 201 countries (referring to populations that are considered as “countries” or “areas” in the UN classification; hence, the expressions “country” and “country/areas” are interchangeable in this appendix) with at least 90,000 inhabitants by mid-2024. The input database is based on a bigger set of countries with 1,000 and above inhabitants by mid-2024.

Table 1 presents the observation distribution by data source for age groups 10–14 and 15–19. The sub-sources within the survey main source type by age group are further listed in Table 2. The data coverage for the majority of countries/areas are good, dating back in the 1960s. Figure 1 summarizes the earliest data available across countries by age group.

At the end of the selection process, we had 15,685 empirical data points available for ages 10–14 (Table 1), covering 224 out of the 236 countries or areas with 1,000 inhabitants or more by mid-2024 (Figure 2). Most of these data were obtained from surveys (49.7%) and register (32.8%), and 17.4% were estimates (which are originated from VR data). Only 14 observations came from censuses (0.1%), which is considerably lower than for the age group 15–19 both in the absolute number and in percentage. The main reason for the difference is that women younger than 15 years are usually not requested to answer questions regarding recent births, and birth data are not tabulated for ages 10–14.

For the age group 15–19, we had a total of 21,017 empirical data points available (Table 1), covering all countries or areas with populations of at least 1,000 inhabitants by mid-2024 (Figure 3). The data were predominantly obtained from surveys (38.0%) and register (36.7%). One-fifth of the data points (20.3%) were estimates. Unlike the age group 10–14, where census data were rare, the age group 15–19 had a substantial number of observations from censuses, with 1,056 observations accounting for 5% of the total.

¹Fertility estimates from some other international survey programs were considered, for example the Performance Monitoring and Accountability (PMA) surveys. Other international survey programs that provided fertility estimates in decades prior to 2010 included the World Fertility Survey (WFS), the Contraceptive Prevalence Surveys (CPS), the Reproductive Health Surveys (RHS), the Pan-Arab Project for Family Health (PAPFAM), and the Pan-Arab Project for Child Development (PAPCHILD).

²The data on number of births and fertility rates are obtained from the United Nations Statistics Division (Demographic Yearbook), national statistical offices and regional ones (e.g., Eurostat, OECD), United Nations Regional Commissions, other United Nations entities (e.g., UNFPA, UNICEF, WHO, World Bank), and complemented using international databases (the Human Fertility Database [2] and Human Fertility Collection [3], the International Data Base [4], the Global Burden of Disease project [5]), and public use microdata archives (e.g., DHS, MICS, IPUMS-International).

Dotted line represents approximately the Line of Control in Jammu and Kashmir agreed upon by India and Pakistan. The final status of Jammu and Kashmir has not yet been agreed upon by the parties. Final boundary between the Republic of Sudan and the Republic of South Sudan has not yet been determined. A dispute exists between the Governments of Argentina and the United Kingdom of Great Britain and Northern Ireland concerning sovereignty over the Falkland Islands (Malvinas).

1.3 Data from birth histories

Among the data coming from surveys (Table 2), for the age group 10–14, more than 5,200 observations came from DHS (67.1% of all survey data) and more than 1,300 observations from MICS (17.6%). For the age group 15–19, DHS also provided the largest proportion of survey data, with 4,687 observations, accounting for 58.7%, while MICS contributed 1,380 observations (17.3%).

In these surveys, women of reproductive age (usually defined as 15 to 49 years) are asked to reconstruct the full list of live births (or pregnancies) they had, including information on the dates of birth. This information on full birth histories permits calculation of age-specific fertility rates (ASFRs) by 3-year or 5-year periods prior to each survey ([7], [8]). Although only women 15–49 are usually eligible in these surveys, all their births were recorded. This makes it possible to compute fertility rates in the age group 10–14 up to 35 years before each survey containing full birth histories. For most time periods, the 10–14 fertility rates were computed in the same way as for the other age groups, by dividing the number of woman-years by the exposure. For the most recent period (3 or 5 years before the survey), the 10–14 fertility rate was computed using the “Lexis approach” proposed by Pullum and colleagues [7].³ Table 3 shows the availability of such data for age groups 10–14 and 15–19. This source of information was particularly important for the assessment of fertility rates for ages 10–14 as it provided estimates for periods of time that were not otherwise covered by VR or censuses.

Age group	Number of years preceding the survey						
	0–4	5–9	10–14	15–19	20–24	25–29	30–34
10–14	470	427	421	414	405	385	371
15–19	473	429	429	426	430	400	0

Table 3: **Number of observations of fertility rates for age groups 10–14 and 15–19 by age group and recall period.** Recall period: 5-year intervals preceding surveys. Note: Observations that were selected from DemoData SQL database (<https://population.un.org/DemoData/web/> for the analysis of ASFRs as of March 2022.

1.4 Most recent data available

Regarding the recency of the empirical evidence, a large majority of the countries or areas with data available had observations for 2015 or later. For 44 countries, the latest data collection for the age group 10–14 occurred in 2014 or earlier (Table 4). Of these, for 19 countries, the most recent data were collected between 2010 and 2014, and for 18 countries, between 2000 and 2009. Among the countries with 90,000 inhabitants or more by mid-2024, 12 had no empirical data available on fertility rates for girls aged 10–14. For ages 15–19, only 25 countries had the most recent data available in 2014 or earlier.

1.5 Data type

We categorised all data sources into five types for data from age groups 10–14 and 15–19 (Table 5). This grouping of data types is used in the model setup where we model the non-sampling errors by data type (detailed in Section 3.1). Specifically, the groupings of data series into five different data source types are:

- Direct estimates of DHS: standard DHS with full birth histories;
- Direct estimates of other DHS-type surveys: Interim DHS, Special DHS, DHS AIDS Indicator Survey, DHS Malaria Indicators Survey, National DHS, World Fertility Survey, and surveys with similar sampling design and based on full birth histories;
- Others direct estimates: census, Reproductive Health Survey (RHS), Pan-Arab Programme on Family Health (PAPFAM), National MICS, panel data, and national reports, based on full birth histories;

³The rate in the age-group 10–14 for the three years before the survey is computed as a weighted average of the single-year rates for ages 12, 13, and 14. The method relies on the assumption that no births occurred before age 12. For the 5 years preceding the survey, the rate is computed as a weighted average of the single-year rates for ages 10, 11, 12, 13, and 14.

Reference year	Age group	
	10–14	15–19
2014 and earlier	44	25
2015	6	7
2016	13	9
2017	11	9
2018	24	19
2019	21	21
2020	17	23
2021	67	69
2022	19	49
2023	2	5
Total	224	236

Table 4: **Number of countries with the latest available ASFR data in age groups 10–14 and 15–19, by 5-year periods preceding the survey.** Note: Observations that were selected from DemoData SQL database (<https://population.un.org/DemoData/web/> for the analysis of ASFRs as of July 2024.

- Indirect estimates: national reports, based on summary birth histories and other model-based and undefined estimates;
- VR or Sample Registration System (SRS).

Data Type	Age group 10–14			Age group 15–19		
	# Countries	# obs.	Proportion of obs. (%)	# Countries	# obs.	Proportion of obs. (%)

2 Data pre-processing

The database we use for model fitting (summarized in Section 1) is based on multiple data quality assessments and pre-processing steps which are detailed in this section.

2.1 Extraction by data source type

Vital registration data The data on the number of births and fertility rates are obtained from the United Nations Statistics Division (Demographic Yearbook), national statistical offices and regional ones (e.g., Eurostat, OECD), United Nations Regional Commissions, other United Nations entities (e.g., UNFPA, UNICEF, WHO, World Bank), and complemented using international databases (the Human Fertility Database [2] and Human Fertility Collection [3]).

Birth and sibling histories in surveys The International Data Base [4], the Global Burden of Disease project [5], and public use microdata archives (e.g., DHS, MICS, IPUMS-International).

Censuses Reports on recent household births were used to compute age-specific estimates. Data from the summary birth histories in censuses were also used for children under five.

2.2 Adjustments for the incompleteness of birth registration

In the first preprocessing step, we computed the stochastic error for VR data. We compiled the number of births by women in a specific age group as the product of the observed fertility rates and the number of women in that age group. The resulting number of births, however, is smaller than the actual one as births are subject to under-reporting. We use the reported birth-reporting completeness (BRC) for country c in year t , denoted as $z_{c,t}$. We assume the reported BRC $z_{c,t}$ to be uniformly distributed. The g -th simulated BRC $z_{c,t}^{(g)}$ is obtained by:

$$z_{c,t}^{(g)} \sim U(z_{c,t} - \delta(z)_{c,t}, z_{c,t} + \delta(z)_{c,t}), \text{ for } g \in \{1, \dots, G\},$$

where $\delta(z)_{c,t}$ is the standard error of reported BRC for country c in year t . It is assumed to increase linearly from 0.05 to 0.25 when the reported BRC $z_{c,t}$ is within the interval [60%, 95%]. When $z_{c,t}$ further increases to 100%, $\delta(z)_{c,t}$ is assumed to further decline linearly to zero. $\delta(z)_{c,t}$ is imputed as:

$$\begin{aligned} \delta(z)_{c,t} &= 0.25 - \frac{0.25 - 0.05}{0.95 - 0.6} (z_{c,t} - 0.6), \text{ if } 60\% \leq z_{c,t} < 95\%, \\ \delta(z)_{c,t} &= 0.05 - \frac{0.05}{1 - 0.95} (z_{c,t} - 0.95), \text{ if } z_{c,t} \geq 95\%. \end{aligned}$$

It is worth noting that the above assumptions made in simulating BRC are largely based on expert opinions. When additional information is available on how $z_{c,t}$ distributes, the simulation steps can be updated accordingly.

The g -th simulated number of under-reported births $B_{c,t}^{\text{under}(g)}$ is calculated as the product of the number of births reported $B_{c,t}^{\text{report}(g)}$ and the difference between 1 and the g -th simulated BRC $z_{c,t}^{(g)}$:

$$B_{c,t}^{\text{under}(g)} = B_{c,t}^{\text{report}(g)} \left(1 - z_{c,t}^{(g)}\right), \text{ for } g \in \{1, \dots, G\}.$$

The g -th simulated total number of births $B_{c,t}^{(g)}$ is the sum of reported births and g -th simulated under-reported births. Uncertainty in the estimates is included by assuming that the simulated number of births has a Poisson distribution:

$$B_{c,t}^{(g)} \sim \text{Poisson} \left(B_{c,t}^{\text{report}(g)} + B_{c,t}^{\text{under}(g)} \right), \text{ for } g \in \{1, \dots, G\}.$$

Compute stochastic error At this point, the g -th simulated number of total births $B_{c,t}^{(g)}$ is divided by the number of women in the specific age group a , denoted as $N_{a,c,t}^{\text{female}}$ to obtain the g -th simulated ASFR of the age group, $F_{a,c,t}^{(g)}$:

$$F_{a,c,t}^{(g)} = B_{c,t}^{(g)} / N_{a,c,t}^{\text{female}}, \text{ for } g \in \{1, \dots, G\}.$$

The stochastic error is the standard deviation of the simulated $F_{a,c,t}^{(g)}$:

$$\sigma_{c,t} = \sqrt{\frac{\sum_{g=1}^G (F_{a,c,t}^{(g)} - \bar{F}_{a,c,t})^2}{G - 1}}, \text{ where } \bar{F}_{a,c,t} = \frac{\sum_{g=1}^G F_{a,c,t}^{(g)}}{G}.$$

Compute sampling error The second preprocessing step entailed the compilation of sampling errors for non-VR data. In this case, we calculated the sampling errors from microdata sets whenever available. If the sampling errors were missing, we imputed them as the median of the sampling errors within each combination of age group and the period before the survey (“recall lag”) for all available observations with sampling errors from microdata sets. To calculate the sampling errors, we generated simulated ASFRs from a normal distribution, with the mean at the observed rates and the standard deviation at the sampling error calculated from the microdata. We finally obtained the sampling error for non-VR data as the computed standard deviation of the simulated fertility rates on the logit scale.

2.3 Exclusion criteria

Before fitting the observations to the Bayesian model, the country analysts reviewed the data sources and data points available. Some of the data points were excluded due to concerns about data quality and completeness. We used the following exclusion criteria to ensure data quality used in our model:

- Exclude ASFR data with outlyingly high values using age-specific cutoffs. Specifically, we only keep ASFR data:
 - Below 0.03 for age group 10–14;
 - Below 0.25 for age group 15–19;
- For VR data, exclude those with low completeness of birth reporting below 60% [6];
- For survey data, exclude data points beyond 35 years before the survey.

3 Methods for age-specific fertility rate 10–19

We provide a full model specification in this web appendix. The modeling procedures to estimate the ASFR for girls aged 10–14 are explained in Section 3.2 and Section 3.4. The modeling procedures to estimate the ASFR for girls and adolescent females aged 15–19 are described in Section 3.1 and Section 3.3. For simplicity, we omit the index for age group, and all the notations in Section 3.1–Section 3.4 are age-specific.

The outcome of interest is $1/(1 + \exp\{-\Psi_{c,t}\})$, ASFR in the country c in year t , where $\Psi_{c,t}$ is the logit of the ASFR. For the country and year indexes, $c \in \{1, \dots, k\}$ with $k = 201$ referring to the total number of countries, and $t \in \{1, \dots, j\}$ with $j = 74$ indicating the individual years from 1950 ($t = 1$) to the year 2023 ($t = j$). Throughout the report, $\mathcal{N}(\mu, \sigma^2)$ refers to a normal distribution with mean μ and variance σ^2 and $\mathcal{U}(a, b)$ refers to a continuous uniform distribution with lower and upper bounds at a and b respectively.

The complete data process and model overview are in the flowchart Figure 4. In particular, Blocks I and II of the flowchart indicates a three-step modeling procedure. This is much improved and straightforward than the Global Burden of Diseases Study (GBD) 2021 ASFR estimation process which involved a six-step modeling process:

1. estimate ASFR for ages 20–24;
2. deriving ASFR for ages 15–19 based on the 20–24 group;
3. adjusting data sources using outputs from previous steps;
4. re-estimating ASFR for ages 20–24 based on adjusted data;
5. recalculating ASFR for ages 15–19; and
6. estimating ASFR for ages 10–14 based on the revised ASFR for ages 15–19

Additionally, the age groups 15–19 and 20–24 have similar data availability and quality across countries and time periods; therefore, there is no strong reasoning based on data availability and quality for inclusion of the steps related to the relationship of 15–19 and 20–24.

The detailed explanations of the model and the posterior distribution are in the rest of this section.

3.1 Data model for age group 15–19

Let z_i to be the i th observed ASFR and $y_i = \text{logit}(z_i)$. We have the model:

$$y_i = \Psi_{c[i],t[i]} + \varepsilon_i, \text{ for } i \in \{1, \dots, n\}, \quad (1)$$

$$\varepsilon_i | \omega_{s[i]} \sim \mathcal{N}(0, u_i^2 + \omega_{s[i]}^2), \text{ independent for } i \in \{1, \dots, n\}, \quad (2)$$

$$\tau_{\omega,s} = \omega_s^{-2} \stackrel{\text{i.i.d.}}{\sim} \mathcal{PC}(w, 0.01), \text{ for } s \in \{1, \dots, m\}. \quad (3)$$

For a certain age group, the observations of ASFR are indexed by $i \in \{1, \dots, n\}$. y_i denotes the i th logit of observed ASFR in country $c[i]$ in year $t[i]$ and is modeled on the logit scale. $1/(1 + \exp\{-\Psi_{c,t}\})$ is the outcome of interest, the true ASFR in country c in year t . ε_i is the error term for y_i .

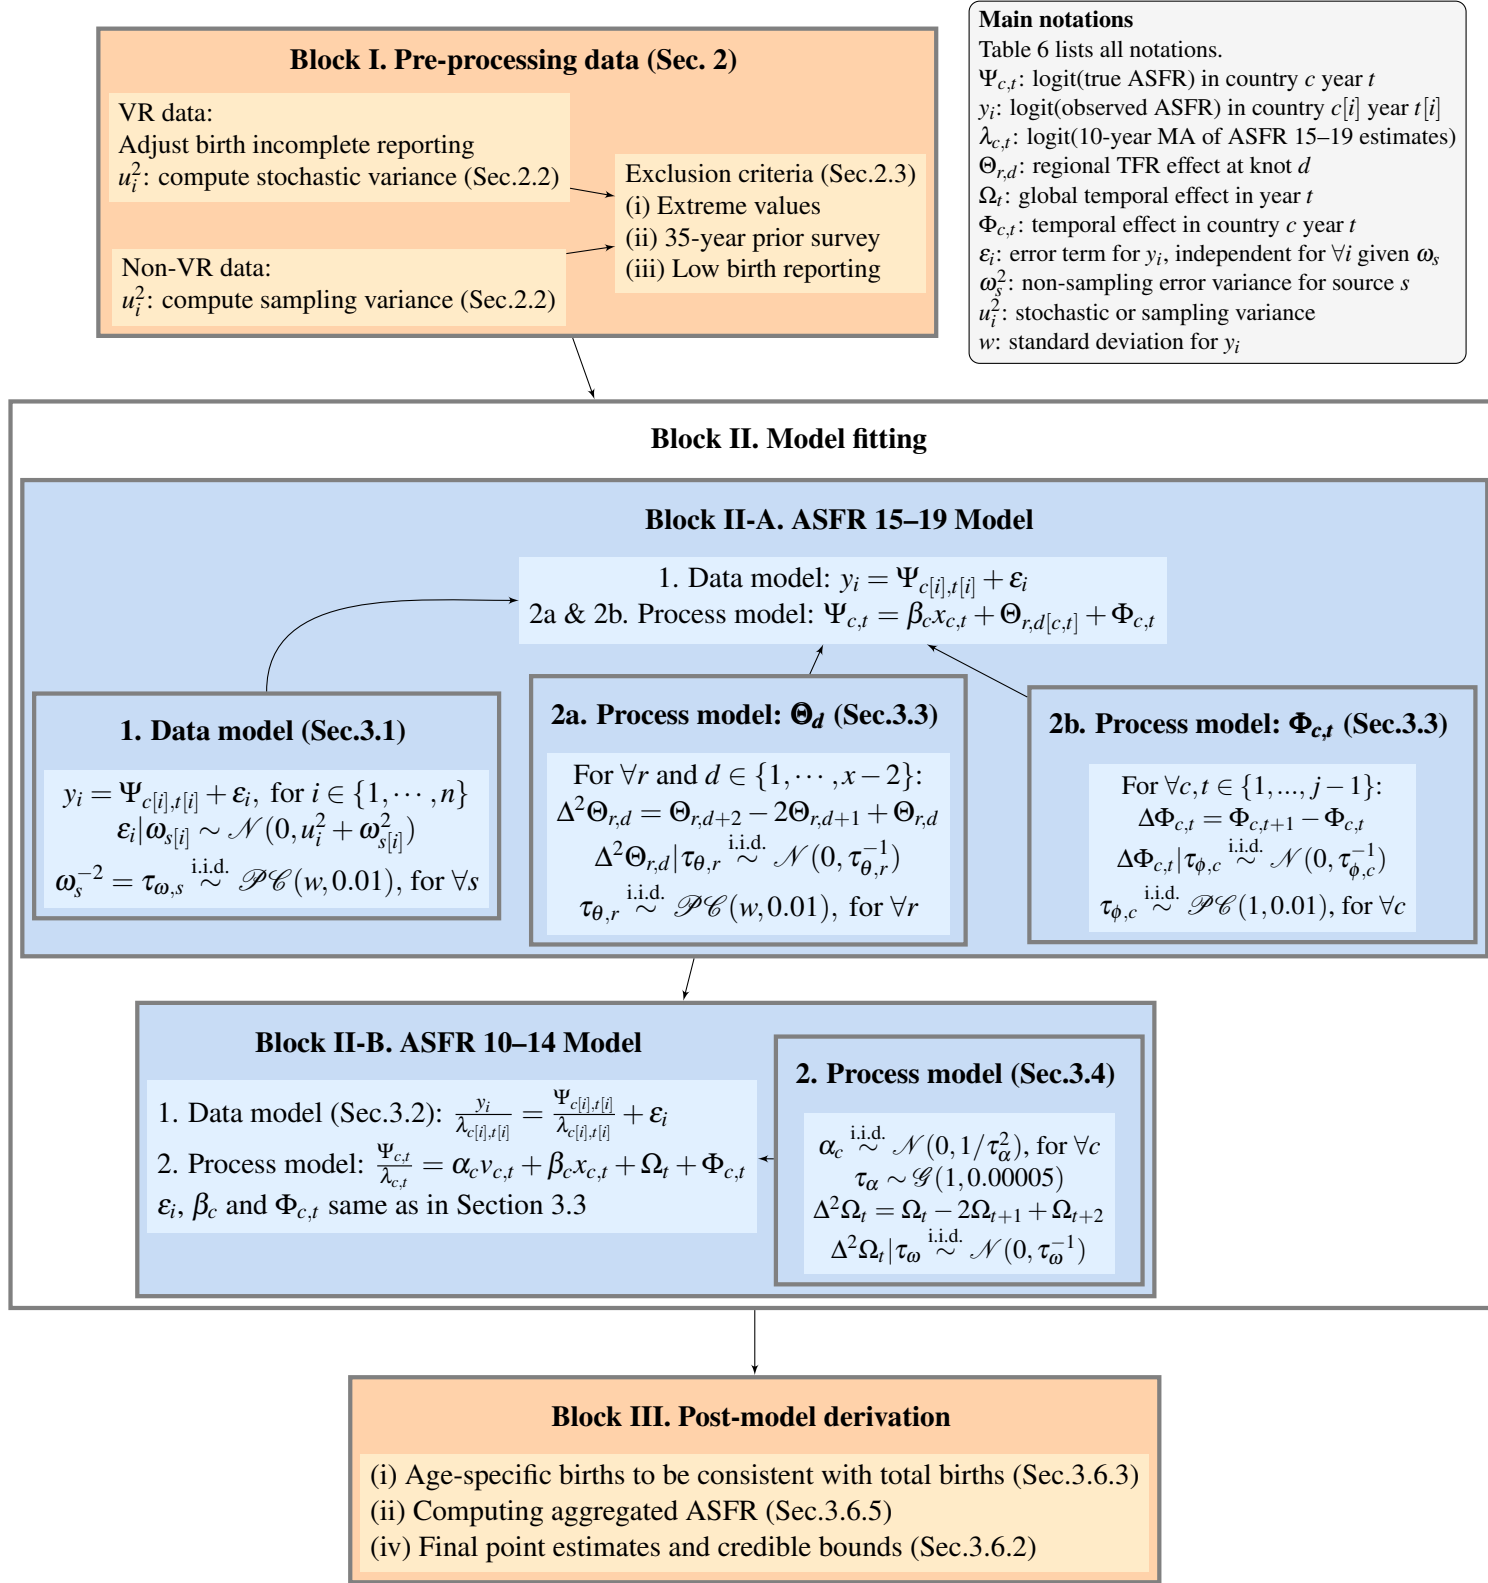

Figure 4: **Data and model process overview.** This flow chart summarizes the major steps of pre-processing data (Block I), the Bayesian modelling steps (Block II), where $\Psi_{c,t}$ refers to the true age-specific fertility rate on the logit-scale, and the post-model derivation (Block III).

The error term ε_i follows a normal distribution as shown in Equation 2. The variance is the sum of two parts: (i) known stochastic/sampling error variance u_i^2 , (ii) unknown non-sampling error variance $\omega_{s[i]}^2$ that differs by data source type s . The sampling variance is pre-calculated using the Jackknife resampling method by the R-package **demogsurv**⁴ to account for the uncertainty due to the sample design of the surveys. We assume the non-sampling error for VR/SRS data is zero (i.e., $s = m$ refers to data source type VR/SRS). For data from non-VR/SRS source types, we estimate non-sampling error variances that vary across data source types ($s \in \{1, \dots, m\}$ refer to the data in m source types). w is the standard deviation of y_i . We assign Penalized Complexity (PC) priors for the precision parameter $\tau_{\omega, s}$ [9].

The Bayesian estimates are pooled towards informative observations and are less influenced by weakly informative observations. Retrospective estimates based on surveys and recent household deaths could be affected by differential underreporting of births in boys or girls. However, comparisons of birth histories in surveys with prospective demographic surveillance did not find that data quality markers were associated with the sex of the child [10].

PC priors are default priors assigned to precision parameters used in the R-package **INLA** [11], which we used for Bayesian inference (refer to Section 3.5, paragraph Statistical computation). The main advantages of PC priors are that they are invariant to reparameterizations and have excellent robustness properties according to Simpson and colleagues [9].

3.2 Data model for age group 10–14

Instead of modeling y_i directly, we model the ratio of logit observed ASFR 10–14 to logit of ASFR median estimates 15–19. Let $\lambda_{c[i], t[i]}$ be the model estimate of ASFR from the age group 15–19 on the logit scale (obtained in Section 3.3). The data model for estimating ASFR from the age group 10–14 is:

$$\frac{y_i}{\lambda_{c[i], t[i]}} = \frac{\Psi_{c[i], t[i]}}{\lambda_{c[i], t[i]}} + \varepsilon_i, \text{ for } i \in \{1, \dots, n\}. \quad (4)$$

Modeling $\frac{y_i}{\lambda_{c[i], t[i]}}$ instead of y_i assists backward projection to 1950 in countries without data in the early period. By doing so, we assume the following:

- Country-specific pattern of ASFR 10–14 is similar to ASFR 15–19 when no data is available for ASFR 10–14 to inform the model, following the assumption made in previous study [12]. Figure 5 shows a positive correlation between ASFR 10–14 and 15–19 across data types and across regions.
- 10-year moving average (MA): to smooth out the year-by-year natural fluctuation while maintaining the levels and trends of the time series. Figure 6 compares between annual time series and 10-year MA for one example country.

ε_i has the same model specifications as described in Section 3.1

3.3 Process model for ASFR 15–19

The process model for $\Psi_{c, t}$, the ASFR for age group 15–19 on logit scale, is defined as:

$$\Psi_{c, t} = \beta_c x_{c, t} + \Theta_{r, d[c, t]} + \Phi_{c, t}, \quad (5)$$

where

- $x_{c, t}$: proportion of female education attainment for country c in year t on log scale;
- β_c : country-specific coefficient for the female education attainment effect;
- $\Theta_{r, d[c, t]}$: regional effect from the total fertility rate (TFR) for country c in year t (more explanations in the next paragraph);
- $\Phi_{c, t}$: year-by-year fluctuation around the global relation, capturing the intra-country temporal correlation between country-specific observations.

⁴Available at: <https://github.com/mrc-ide/demogsurv>. Accessed on July 27th, 2020.

Figure 5: Scatter plots between ASFR 10–14 and 15–19 observations, by data type (top) and by region (bottom).

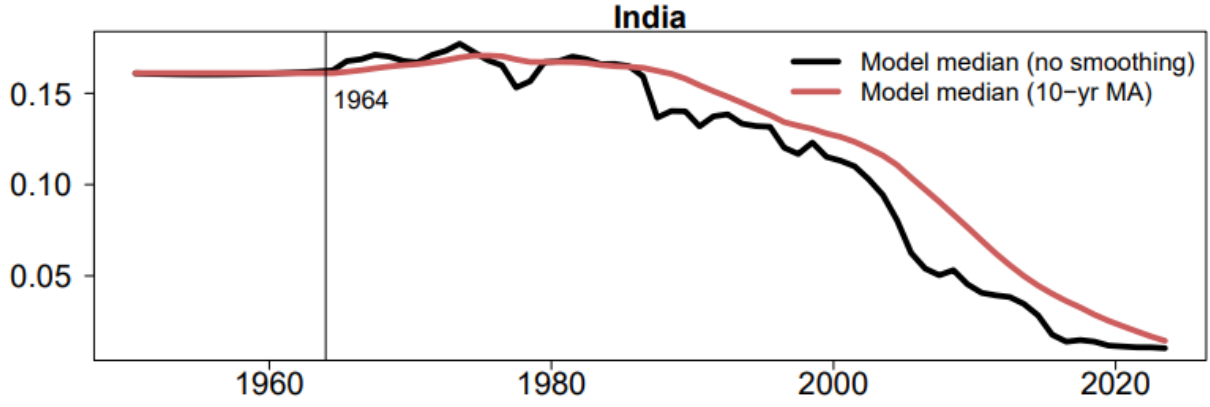

Figure 6: **Illustration of $\lambda_{c,t}$ as input data for model 10–14 for one country.** Black curve: median estimates of ASFR 15–19 without smoothing. Red curve: 10-year moving average of the median estimates of ASFR 15–19 as input data for modeling ASFR 10–14, corresponding to $\lambda_{c,t}$ in Equation 4.

β_c is the country-level fixed effect of female education attainment. It follows a hierarchical normal distribution with mean at zero and a global precision parameter:

$$\beta_c | \tau_\beta \stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, 1/\tau_\beta), \text{ for } c \in \{1, \dots, k\}. \quad (6)$$

We assign non-informative priors to the global precision parameter τ_β :

$$\tau_\beta \sim \mathcal{G}(1, 0.00005). \quad (7)$$

$\Theta_{r,d[c,t]}$ models the regional non-linear relation between $\Psi_{c,t}$ and the TFR in country c , year t . Specifically, let $v_{c,t}$ denote the log of TFR for country c year t , taken from the UN WPP 2024 estimates [1]. We define a grid of values κ_d for $d \in \{1, \dots, x\}$. $x = 150$ is the number of grid points where $\Theta_{r,d}$ is evaluated. Let $\kappa_1 = \log(0.7)$, the minimum $v_{c,t}$, corresponding to 0.7 birth per 1,000 population on the log scale. We set $\kappa_x = \log(8.1)$ as the 99.5th percentile of $v_{c,t}$ across all country-years with data. We match each $v_{c,t}$ to the κ_d with the smallest absolute difference from $v_{c,t}$, denoting the d th index for country-year c, t as $d[c, t]$. To model the relation between $\Theta_{r,d}$ and κ_d , we use a second-order random walk (RW2) process. We assume $\Theta_{r,d}$ is constant outside the range of κ_1 and κ_x across all c and t . In particular,

$$\Delta^2 \Theta_{r,d} = \Theta_{r,d+2} - 2\Theta_{r,d+1} + \Theta_{r,d}, \text{ for } r \in \{1, \dots, p\} \text{ and } d \in \{1, \dots, x-2\} \quad (8)$$

$$\Delta^2 \Theta_{r,d} | \tau_{\theta,r} \stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_{\theta,r}^{-1}), \text{ for } r \in \{1, \dots, p\} \text{ and } d \in \{1, \dots, x-2\}. \quad (9)$$

We assign a Penalized Complex (PC) prior to the regional precision parameter $\tau_{\theta,r}$:

$$\tau_{\theta,r} \stackrel{\text{i.i.d.}}{\sim} \mathcal{PC}(w, 0.01), \text{ for } r \in \{1, \dots, p\}. \quad (10)$$

where w is the standard deviation of y_i . The PC prior is a vague prior. The paper by Simpson et al. [9] documented the PC prior specification in detail. Figure 7 illustrates the RW2 model results for $\Theta_{r,d}$, the regional TFR effects on ASFR, for age group 15–19.

$\Phi_{c,t}$ models the country-specific temporal effects. We use a first-order random walk (RW1) model for $\Phi_{c,t}$ and assign a PC prior to country-specific precision parameter $\tau_{\phi,c}$:

$$\Delta \Phi_{c,t} = \Phi_{c,t+1} - \Phi_{c,t}, \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j-1\} \quad (11)$$

$$\Delta \Phi_{c,t} | \tau_{\phi,c} \stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_{\phi,c}^{-1}), \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j-1\}, \quad (12)$$

$$\tau_{\phi,c} \stackrel{\text{i.i.d.}}{\sim} \mathcal{PC}(1, 0.01), \text{ for } c \in \{1, \dots, k\}. \quad (13)$$

The sum-to-zero constraint is imposed on $\Phi_{c,t}$ so that the precision matrix is full-rank:

$$\sum_{t=1}^j \Phi_{c,t} = 0, \text{ for } c \in \{1, \dots, k\}. \quad (14)$$

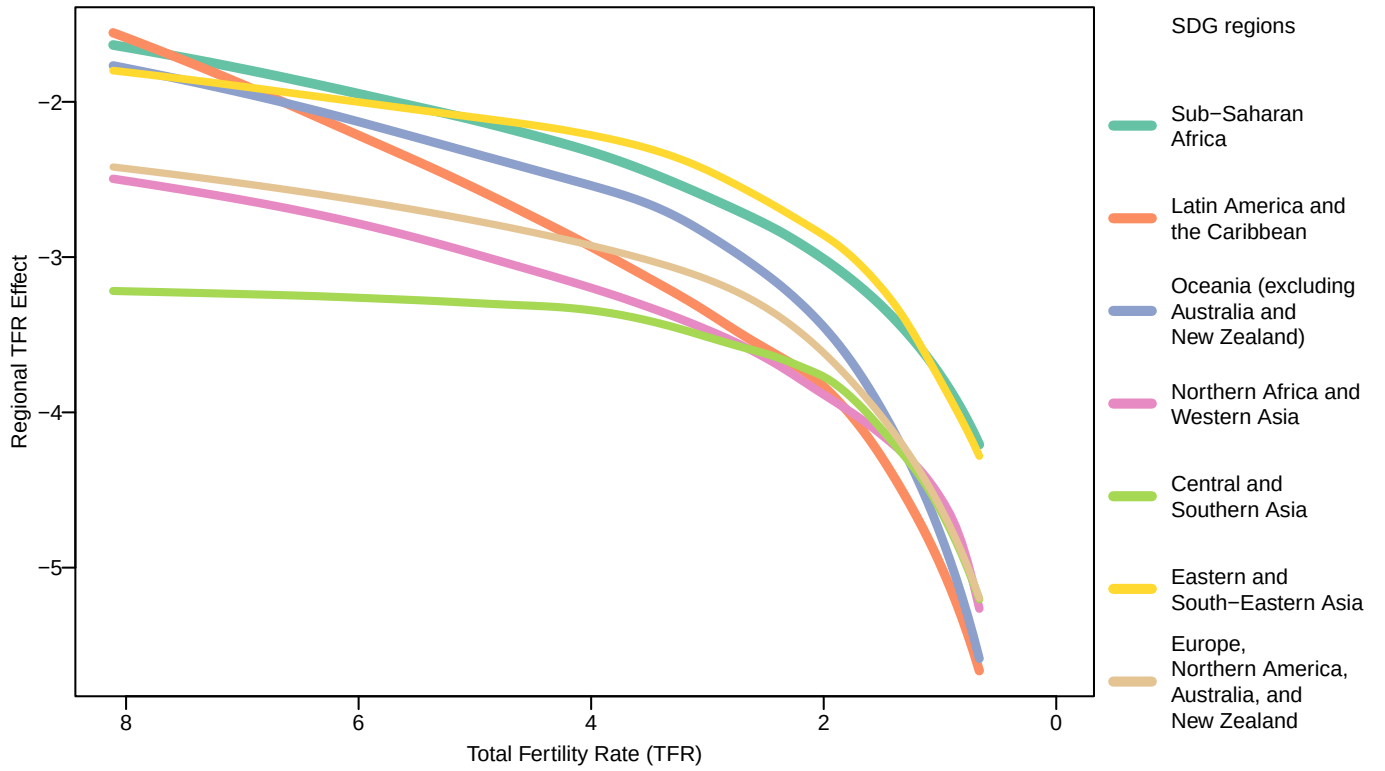

Figure 7: **Regional relation between TFR and ASFR 15–19.** The model median estimates for the TFR effect from different regions are differentiated by colors. TFR: total fertility rate. ASFR: age-specific fertility rate.

3.4 Process model for ASFR 10–14

The process model for logit of ASFR for age group $a=10-14$, denoted as $\Psi_{c,t}$, is defined as:

$$\frac{\Psi_{c,t}}{\lambda_{c,t}} = \alpha_c v_{c,t} + \beta_c x_{c,t} + \Omega_t + \Phi_{c,t}, \quad (15)$$

where

- $\lambda_{c,t}$: logit of the 10-year moving average (MA) of ASFR 15–19 medians obtained in Section 3.3 (more explanations below);
- $v_{c,t}$: TFR for country c in year t on log scale;
- α_c : country-specific coefficient for the TFR effect;
- $x_{c,t}$: proportion of female education attainment for country c in year t on log scale;
- β_c : country-specific coefficient for the female education attainment effect;
- Ω_t : global time trend in year t ;
- $\Phi_{c,t}$: year-by-year fluctuation around the global relation, capturing the intra-country temporal correlation between country-specific observations.

The country-specific parameters β_c and $\Phi_{c,t}$ are modeled the same as in Section 3.3. The country-specific regression coefficients α_c follow a hierarchical distribution with a non-informative prior assigned to its global precision parameter τ_α :

$$\alpha_c | \tau_\alpha \stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, 1/\tau_\alpha^2), \text{ for } c \in \{1, \dots, k\}, \quad (16)$$

$$\tau_\alpha \sim \mathcal{G}(1, 0.00005). \quad (17)$$

Ω_t models the global non-linear relation between ASFR and time with a random walk model of order 2 (RW2):

$$\Delta^2 \Omega_t = \Omega_t - 2\Omega_{t+1} + \Omega_{t+2}, \quad (18)$$

$$\Delta^2 \Omega_t | \tau_\omega \stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_\omega^{-1}), \text{ for } t \in \{1, \dots, j-2\}, \quad (19)$$

$$\tau_\omega \sim \mathcal{PC}(1, 0.01). \quad (20)$$

3.5 Model summary

Notations Table 6 summarizes the notation and indexes used in Section 3.1, 3.2, 3.3, and 3.4.

Data model 15–19

$$\begin{aligned} y_i &= \Psi_{c[i],t[i]} + \varepsilon_i, \text{ for } i \in \{1, \dots, n\}, \\ \varepsilon_i | \omega_{s[i]} &\sim \mathcal{N}(0, u_i^2 + \omega_{s[i]}^2), \text{ independent for } i \in \{1, \dots, n\}. \end{aligned}$$

Process model 15–19

$$\begin{aligned} \Psi_{c,t} &= \beta_c x_{c,t} + \Theta_{r,d[c,t]} + \Phi_{c,t}, \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j\}, \\ \beta_c | \tau_\beta &\stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, 1/\tau_\beta), \text{ for } c \in \{1, \dots, k\}, \\ \Delta^2 \Theta_{r,d} &= \Theta_{r,d+2} - 2\Theta_{r,d+1} + \Theta_{r,d}, \text{ for } r \in \{1, \dots, p\} \text{ and } d \in \{1, \dots, x-2\}, \\ \Delta^2 \Theta_{r,d} | \tau_{\theta,r} &\stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_{\theta,r}^{-1}), \text{ for } r \in \{1, \dots, p\} \text{ and } d \in \{1, \dots, x-2\}, \\ \Delta \Phi_{c,t} &= \Phi_{c,t+1} - \Phi_{c,t}, \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j-1\}, \\ \Delta \Phi_{c,t} | \tau_{\phi,c} &\stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_{\phi,c}^{-1}), \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j-1\}. \end{aligned}$$

Prior distributions 15–19 Non-informative priors are assigned to hyper-parameters:

$$\begin{aligned} \tau_{\omega,s} = \omega_s^{-2} &\stackrel{\text{i.i.d.}}{\sim} \mathcal{PC}(w, 0.01), \text{ for } s \in \{1, \dots, m\}, \\ \tau_\beta &\sim \mathcal{G}(1, 0.00005), \\ \tau_{\theta,r} &\stackrel{\text{i.i.d.}}{\sim} \mathcal{PC}(w, 0.01), \text{ for } r \in \{1, \dots, p\}, \\ \tau_{\phi,c} &\stackrel{\text{i.i.d.}}{\sim} \mathcal{PC}(1, 0.01), \text{ for } c \in \{1, \dots, k\}. \end{aligned}$$

Data model 10–14

$$\begin{aligned} \frac{y_i}{\lambda_{c[i],t[i]}} &= \frac{\Psi_{c[i],t[i]}}{\lambda_{c[i],t[i]}} + \varepsilon_i, \text{ for } i \in \{1, \dots, n\}, \\ \varepsilon_i | \omega_{s[i]} &\sim \mathcal{N}(0, u_i^2 + \omega_{s[i]}^2), \text{ independent for } i \in \{1, \dots, n\}, \\ \tau_{\omega,s} = \omega_s^{-2} &\stackrel{\text{i.i.d.}}{\sim} \mathcal{PC}(w, 0.01), \text{ for } s \in \{1, \dots, m\}. \end{aligned}$$

Symbol	Description
<i>Indexes</i>	
i	Indicator for observations across all country-years, $i \in \{1, \dots, n\}$.
r	Indicator for region, $r \in \{1, \dots, p\}$, where $p = 7$.
c	Indicator for country, $c \in \{1, \dots, k\}$, where $k = 201$. $c[i]$ refers to the country index of observation i .
t	Indicator for year, $t \in \{1, \dots, j\}$, where $j = 74$. $t = 1$ corresponds to the year 1950 and $t = j$ to the year 2023. $t[i]$ refers to the year index of observation i .
s	Indicator for data source type, $s \in \{1, \dots, m\}$, where $m = 5$. Refer to Table 17 and 18 for data sources.
d	Indicator for the d -th unique value of the total fertility rate (TFR) κ_d and corresponding regional TFR effect $\Theta_{r,d[c,t]}$. $d[c,t]$ refers to the index based on TFR in country-year c, t . More explanations are in the row of κ_d .
<i>Known quantities</i>	
z_i	i th observed age-specific fertility rate (ASFR) for country $c[i]$ in year $t[i]$ with data source type $s[i]$.
y_i	$y_i = \text{logit}(z_i)$.
u_i^2	The i th sampling error variance for y_i .
w	The standard deviation of y_i .
$Q_{c,t}$	The TFR median estimate for country c in year t from the UN WPP [1].
$v_{c,t}$	$v_{c,t} = \log(Q_{c,t})$
$x_{c,t}$	The proportion of female education attainment for country c in year t on log scale [13].
κ_d	Grid of $v_{c,t}$ where $\Theta_{r,d}$ is evaluated for $d \in \{1, \dots, x\}$, and $x = 150$. $\kappa_1 = \log(0.7/1000)$, i.e. $\log$ of 0.7 birth per 1000 population. $\kappa_x = \log(8.1/1000)$ is the 99.5th percentile of $v_{c,t}$ across all country-years with data.
$\lambda_{c,t}$	logit of the 10-year moving average (MA) of ASFR 15–19 medians obtained in Section 3.3
<i>Unknown parameters</i>	
$\Psi_{c,t}$	The true logit of ASFR for country c , year t .
Ω_t	global time trend in year t .
$\Theta_{r,d[c,t]}$	The regional TFR effect evaluated at κ_d for country c , year t .
$\Phi_{c,t}$	The year-by-year within country discrepancy between $\Psi_{c,t}$ and $\Theta_{r,d}$.
α_c	country-specific coefficient for the TFR effect.
β_c	country-specific coefficient for the female education attainment effect.
$\tau_{\omega,s}$	The precision parameter for non-sampling error variance with data source type s .
$\tau_{\theta,r}$	The precision parameter for the second-order increment $\Delta^2 \Theta_{r,d}$.
$\tau_{\phi,c}$	The country-specific precision parameter for the first-order increment $\Delta \Phi_{c,t}$ for country c .

Table 6: **Notation summary.**

Process model 10–14

$$\begin{aligned}
\frac{\Psi_{c,t}}{\lambda_{c,t}} &= \alpha_c v_{c,t} + \beta_c x_{c,t} + \Omega_t + \Phi_{c,t}, \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j\}, \\
\Delta^2 \Omega_t &= \Omega_t - 2\Omega_{t+1} + \Omega_{t+2}, \text{ for } t \in \{1, \dots, j-2\}, \\
\Delta^2 \Omega_t | \tau_\omega &\stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_\omega^{-1}), \text{ for } t \in \{1, \dots, j-2\}, \\
\Delta \Phi_{c,t} &= \Phi_{c,t+1} - \Phi_{c,t}, \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j-1\}, \\
\Delta \Phi_{c,t} | \tau_{\phi,c} &\stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \tau_{\phi,c}^{-1}), \text{ for } c \in \{1, \dots, k\}, t \in \{1, \dots, j-1\}, \\
\alpha_c | \tau_\alpha &\stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, 1/\tau_\alpha^2), \text{ for } c \in \{1, \dots, k\}, \\
\beta_c | \tau_\beta &\stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, 1/\tau_\beta^2), \text{ for } c \in \{1, \dots, k\}.
\end{aligned}$$

Prior distributions 10–14 Non-informative priors are assigned to hyper-parameters:

$$\begin{aligned}
\tau_{\phi,c} &\stackrel{\text{i.i.d.}}{\sim} \mathcal{PC}(1, 0.01), \text{ for } c \in \{1, \dots, k\}, \\
\tau_\omega &\sim \mathcal{PC}(1, 0.01), \\
\tau_\alpha &\sim \mathcal{G}(1, 0.00005), \\
\tau_\beta &\sim \mathcal{G}(1, 0.00005).
\end{aligned}$$

Statistical computation We use the Integrated Nested Laplace Approximation (INLA) for Bayesian inference [14]. We use the R-package R-INLA [11] to implement the INLA estimation procedure. The statistical source code is available upon request.

3.6 Computation of final results

Throughout the project, we presented our results in the format of “point estimate [lower bound; upper bound]”. E.g. the ASFR and births are presented as $Q_{a,c,t}^{\text{PE}}[Q_{a,c,t}^{\text{L}}; Q_{a,c,t}^{\text{U}}]$ and $B_{a,c,t}^{\text{PE}}[B_{a,c,t}^{\text{L}}; B_{a,c,t}^{\text{U}}]$ respectively. This section will explain how we derived each component in the result.

3.6.1 Rounding

We kept three significant figures for all reported estimates and uncertainty intervals. We round the number of births by mothers from different age groups for each country-year to its nearest integer.

3.6.2 Constructing uncertainty intervals and point estimates

The uncertainties from TFR were incorporated into the final uncertainties of the ASFR. For the g -th trajectory of the ASFR for age 15–19 on the logit scale $\Psi_{c,t}^{(g)}$, with $g \in \{1, \dots, G\}$, it is obtained as:

$$\Psi_{c,t}^{(g)} = \beta_c^{(g)} x_{c,t} + \Theta_{r,d[c,t]}^{(g)} + \Phi_{c,t}^{(g)},$$

where $\beta_c^{(g)}$ and $\Phi_{c,t}^{(g)}$ are the g -th trajectories of the model parameters β_c and $\Phi_{c,t}$, obtained directly from the Bayesian model itself as posterior samples. $\Theta_{r,d[c,t]}^{(g)}$ is the g -th trajectory of the TFR regional effect based on the g -th trajectory of the TFR $Q_{c,t}^{(g)}$. The TFR trajectories are from the UN WPP [1].

For the g -th trajectory of the ASFR for age 10–14 on the logit scale $\Psi_{c,t}^{(g)}$, with $g \in \{1, \dots, G\}$, it is obtained as:

$$\Psi_{c,t}^{(g)} = \left(\alpha_c^{(g)} v_{c,t}^{(g)} + \beta_c^{(g)} x_{c,t} + \Omega_t^{(g)} + \Phi_{c,t}^{(g)} \right) \lambda_{c,t}^{(g)},$$

where $\alpha_c^{(g)}$, $\beta_c^{(g)}$, $\Omega_t^{(g)}$ and $\Phi_{c,t}^{(g)}$ are the g -th trajectories of the model parameters α_c , β_c , Ω_t , and $\Phi_{c,t}$, obtained directly from the Bayesian model itself as posterior samples. $v_{c,t}^{(g)}$ is the g -th trajectory of the TFR on the log scale $\log(Q_{c,t}^{(g)})$. The TFR trajectories are from the UN WPP [1]. Whereas $\lambda_{c,t}^{(g)}$ is the g -th trajectory of the 10-year moving average of logit ASFR 15–19 obtained above.

All the indicators in this section are country-year-specific. Hence, we omit the indexes c and t for country and year for simplicity. The 95% uncertainty intervals for $\Psi(\text{full})_a$, $Q(\text{full})_a$, and $B(\text{full})_a$, denoted as $[*^L; *^U]$, are the 2.5th and 97.5th percentiles of the corresponding posterior samples:

$$\begin{aligned} *^L &= \text{percentile}_{2.5\%} \left\{ {}^{(1)}*, \dots, {}^{(G)}* \right\}, \\ *^U &= \text{percentile}_{97.5\%} \left\{ {}^{(1)}*, \dots, {}^{(G)}* \right\}. \end{aligned}$$

where $*$ can be substituted with $\Psi(\text{full})_a$, $Q(\text{full})_a$, and $B(\text{full})_a$.

The point estimates $\exp\{\Psi(\text{full})\}_a^{\text{PE}}$ are combined with the point estimates of total fertility rate $Q(\text{full})_a^{\text{PE}}$ and the number of total births $B(\text{full})_a^{\text{PE}}$ (both were obtained from the UN WPP 2024 results [1], not part of the modelling process) to derive the point estimates of age-specific births $B(\text{full})_a^{\text{PE}}$.

To assess the uncertainty with respect to the point estimates, we calculated the coefficient of variance (CV). For the CV of the Bayesian model result from age group a in country c and year t , we have:

$$\text{CV}_{a,c,t} = \frac{Q_{a,c,t}^U - Q_{a,c,t}^L}{4Q_{a,c,t}^{\text{PE}}},$$

where four standard errors is assumed to fall between the lower bound $Q_{a,c,t}^L$ and upper bound $Q_{a,c,t}^U$ of the point estimate $Q_{a,c,t}^{\text{PE}}$.

3.6.3 Age-specific births to be consistent with total births

Due to rounding (Section 3.6.1) and the different data availability and quality between the ASFR and the TFR, the sum of the births by mothers from different age groups for a particular country-year $\sum_a B(\text{full})_a^{\text{PE}}$ may be slightly different than the total births for the same country-year $B(\text{full})^{\text{PE}}$, where total births computation is not part of the modelling process. When the inconsistency occurs for a certain country-year, we:

- compute the ratio of $B(\text{full})^{\text{PE}}$ to $\sum_a B(\text{full})_a^{\text{PE}}$
- apply the ratio to the trajectories of $B(\text{full})_a^{(g)}$ for $g \in \{1, \dots, G\}$.

This adjustment is typically small but ensures that $\sum_a B(\text{full})_a^{\text{PE}} = B(\text{full})^{\text{PE}}$ for all country-years. We adjust both the point estimates and the uncertainty intervals.

3.6.4 Annual rate of reduction

The annual rate of reduction (ARR) for country c during the period of $[t_1, t_2]$ is defined as

$$\text{ARR}_{c,[t_1,t_2]} = \frac{\log(\Psi_{t_2}/\Psi_{t_1})}{t_1 - t_2}, \text{ with } t_1 < t_2.$$

Ψ_{t_1} and Ψ_{t_2} refer to the model estimates for the ASFR in years t_1 and t_2 respectively.

For country-years with ASFR in ages 10–14 and 15–19 below 0.01 per 1000 females, we use 0.01 per 1,000 for that country-year when computing the ARR. If the maximum values of the posterior samples of ASFR in both years t_1 and t_2 are below 0.01 per 1,000, i.e. $\Psi_{t_1} < 10^{-5}$ and $\Psi_{t_2} < 10^{-5}$, then we assume the changes are largely stochastic rather than actual changes and we consider $\text{ARR}_{c,[t_1,t_2]} = 0$ for that period.

If the median ASFRs in both years t_1 and t_2 are below 0.1 per 1,000, i.e. $\Psi_{t_1} < 10^{-4}$ and $\Psi_{t_2} < 10^{-4}$, then we do not report the ARR results for that location-period and assume most changes are stochastic.

3.6.5 Computing aggregated results

The 201 countries or areas with total population larger than 90,000 by mid-2024 (according to the UN WPP 2024 population estimates [1]) were aggregated following the regional grouping in Table 12. The number of births by age group of the mother from region r for the a -th age group for year t , denoted by $BR_{a,r,t}$, was computed as:

$$BR_{a,r,t} = \sum_{c \in \{\text{region}[c]=r\}} B(\text{full})_{a,c,t}, \text{ for } r \in \{1, \dots, p\}.$$

The ASFR from region r for the a -th age group for year t , denoted by $QR_{a,r,t}$, was computed as:

$$QR_{a,r,t} = QR(\text{full})_{r,t} \cdot \frac{BR_{a,r,t} \cdot 5}{BR(\text{full})_{r,t}}, \text{ for } r \in \{1, \dots, p\},$$

where

$$BR(\text{full})_{r,t} = \sum_{c \in \{\text{region}[c]=r\}} B(\text{full})_{c,t}.$$

$QR(\text{full})_{r,t}$ is the aggregated TFR from region r in year t from the UN WPP 2024 results [1].

4 Validation exercise and results

We validate the model performance by leaving out data collected after a particular year, referred to as the “survey year”, rather than randomly leaving out data. This validation approach has been used in various previous global health and population studies [15, 16, 17, 18, 19, 20, 21, 22, 23]. The left-out observations are roughly 20% of the total observations (due to the varying number of observations collected in each survey year, the left-out observations can be slightly above or below 20%). We call the left-out observations “testing dataset” and the remaining observations “training dataset”.

For each left-out observation in the testing dataset, we generate a posterior predictive distribution based on the Bayesian model fittings for the training dataset. We compute the error as the difference between the left-out observation and the median of the posterior predictive distribution. We report the median errors of all the left-out observations and the median of the absolute errors. We also report the coverage of the 90% prediction intervals (PIs). The lower and upper bounds of the 90% PI for each left-out observation is the 5th and 95th percentiles of the posterior predictive distribution. To summarise the coverage, we compute the proportion of left-out observations that fall outside the 90% PIs in Table 7. Median errors are close to zero for left-out observations in both age groups. While the errors can be negative or positive and are usually distributed around zero (if the model is well calibrated, as shown in Table 7), the absolute errors can only be positive because it is the absolute values of the errors. Hence, the median absolute errors in all age groups are expected to be higher than the median errors. Coverage of 90% prediction intervals is slightly higher than expected at 96.2% for the age group 10–14 and 91.3% for the age group 15–19.

We also validate the model performance by comparing the model estimates based on the full and training datasets. We compute the error for each country-year as the difference between the median estimates based on the full dataset and those based on the training dataset. We report the median of these errors and absolute errors for all the country-years. We check the percentage of the country-years where the median estimates based on the full dataset fall outside the credible bounds of the estimates based on the training dataset. Table 8 shows the results for the comparison between estimates obtained based on the full dataset and estimates based on the training set. Median errors and median absolute errors were close to zero, and the proportion of updated estimates that fell outside the uncertainty intervals constructed based on the training set was mostly within the expected level (less than 5%). The exception is the median estimates based on the full run tend to be higher than the 90% credible interval (CI) based on the training database. This implies that the recent data show that the ASFR from age 15–19 declined faster than the historical experience based on the model assumptions.

Age group	10–14	15–19
Median error	0.000	-0.001
Median absolute error	0.001	0.013
% of left-out observations below 90% prediction interval	4.4	6.0
% of left-out observations above 90% prediction interval	1.4	2.7
Expected proportions (%)	5.0	5.0
# left out observations	3,385	3,795
% of left out to total observations	15.4	17.7
Survey year left out	2013	2012

Table 7: **Validation results for left-out observations by age group.** Errors are defined as the difference between a left-out observation and the posterior median of its predictive distribution. Survey year left out: left out all observations that were collected in or after the year.

Age group Year	10–14			15–19		
	2000	2005	2010	2000	2005	2010
Median error	0.000	0.000	0.000	0.000	0.000	0.000
Median absolute error	0.000	0.000	0.000	0.002	0.002	0.002
Below 90% uncertainty interval (%)	3.0	5.1	3.0	2.1	3.8	3.0
Above 90% uncertainty interval (%)	3.0	3.8	5.1	8.0	7.2	7.2
Expected proportions (%)	≤5	≤5.0	≤5.0	≤5.0	≤5.0	≤5.0

Table 8: **Summary of differences in ASFR estimates in observation years 2000, 2005, and 2010 based on the training and full data sets.** Errors are the differences between estimates based on the full dataset and the training set. The proportions refer to the proportions (%) of countries where the median ASFR estimates based on the full data set fall below or above their corresponding 90% uncertainty intervals based on the training dataset. The results are broken down by age groups and observation years.

5 Sensitivity analyses

In addition to the validation exercises (Section 4), we conducted sensitivity analyses in this section to test model assumptions. Essentially, two widely accepted criteria of Bayesian model assessment and comparison were used, namely Deviance Information Criterion (DIC) and Watanabe-Akaike Information Criterion (WAIC). In addition, we checked the cross-validation and predictive measures of fit using the Conditional Predictive Ordinates (CPO) to strengthen the model assessment and comparison.

5.1 Time series model setup

As presented in Section 3.3, an RW1 model is used to estimate the country-specific temporal effects $\Phi_{c,t}$. We tested another model with all other model assumptions remains unchanged, the only change is to use an autoregressive of order 1 (AR1) model for $\Phi_{c,t}$. That is,

$$\begin{aligned}
\Phi_{c,t} &= \rho \Phi_{c,t-1} + \varepsilon_{c,t}, \text{ with } |\rho| < 1, \text{ for } c \in \{1, \dots, k\}, t \in \{2, \dots, j\} \\
\Phi_{c,t} &\sim \mathcal{N}(0, \frac{\sigma_\varepsilon^2}{1 - \rho^2}), \text{ for } t = 1, \\
\varepsilon_{c,t} | \sigma_\varepsilon &\stackrel{\text{i.i.d.}}{\sim} \mathcal{N}(0, \sigma_\varepsilon^2).
\end{aligned}$$

with weakly informative priors assigned to $1/\sigma_\varepsilon^2$ and ρ .

We compared the DIC, WAIC, and CPO for the two models in Table 9. A model with smaller DIC or WAIC should be preferred to one with larger DIC or WAIC. Whereas for CPO, a larger value indicates a model with better fit than one with a smaller CPO. Both DIC and CPO suggest the original model with RW1 time series setup for $\Phi_{c,t}$

is better than the alternative model with AR1 setup. Meanwhile, the CPO values from both models are very similar to each other.

Model	DIC	WAIC	CPO
Original (RW1)	-33,408	-32,173	129,62
Alternative (AR1)	-33,401	-32,204	129,53

Table 9: **Model comparison for time series setup.** $CPO = \sum_{i=1}^n \log(cpo_i)$.

5.2 ASFR 10–14 model setup

As explained in Section 3.4, the ASFR 10–14 estimation made use of the pattern of the ASFR 15–19 to assist in providing more plausible results.

To test this model assumption, we conducted model diagnostics and checks between two models:

- Original model for ASFR 10–14: as described in Section 3.4.
- Alternative model for ASFR 10–14: the same model as for ASFR 15–19 without using ASFR pattern from the neighbouring age group as described in Section 3.3.

We compared the DIC, WAIC, and the CPO for the two models in Table 10. All three criteria suggest the original model has better fits than the alternative model.

Model 10–14	DIC	WAIC	CPO
Original	-6,511	-4,045	919
Alternative	20,324	23,052	-13,175

Table 10: **Model comparison for time series setup.** $CPO = \sum_{i=1}^n \log(cpo_i)$. Original model for ASFR 10–14: as described in Section 3.4. Alternative model for ASFR 10–14: the same model as for ASFR 15–19 without using ASFR pattern from the neighbouring age group as described in Section 3.3.

In addition to the better model fit for the original model than the alternative model, there are two other reasons we chose the original model against the alternative model:

1. The original model provides narrower uncertainty bounds for country-periods without data than the alternative model: Figure 8 top.
2. The original model provides more realistic backward projections in countries known to have high teenage fertility rate than the alternative model: Figure 8 bottom.

6 Uncertainty assessments of model results

The uncertainty bound with respect to the estimated ASFR level can be wide due to: (i) lack of data in the early period, or (ii) close-to-zero estimates in the recent period. The coefficient of variance (CV) across all country-years are presented in Figure 9 for ages 10–14 and in Figure 10 for ages 15–19.

The CVs for ages 15–19 in all country-years of the model results are good as shown in Figure 10. The maximum CV is below 0.6.

The CVs for ages 10–14 have a wider spectrum than the older age group as shown in Figure 9. The countries are identified according to the country-specific mean CVs, denoted as $\overline{CV}_{a,c} = \sum_{t=1950}^{2023} CV_{a,c,t} / (2023 - 1950 + 1)$. The main reasons of causing the high CVs are:

- i. No data;
- ii. Limited data;
- iii. Close-to-zero point estimates of ASFR;
- iv. ASFR observations are weakly informative with large sampling errors;

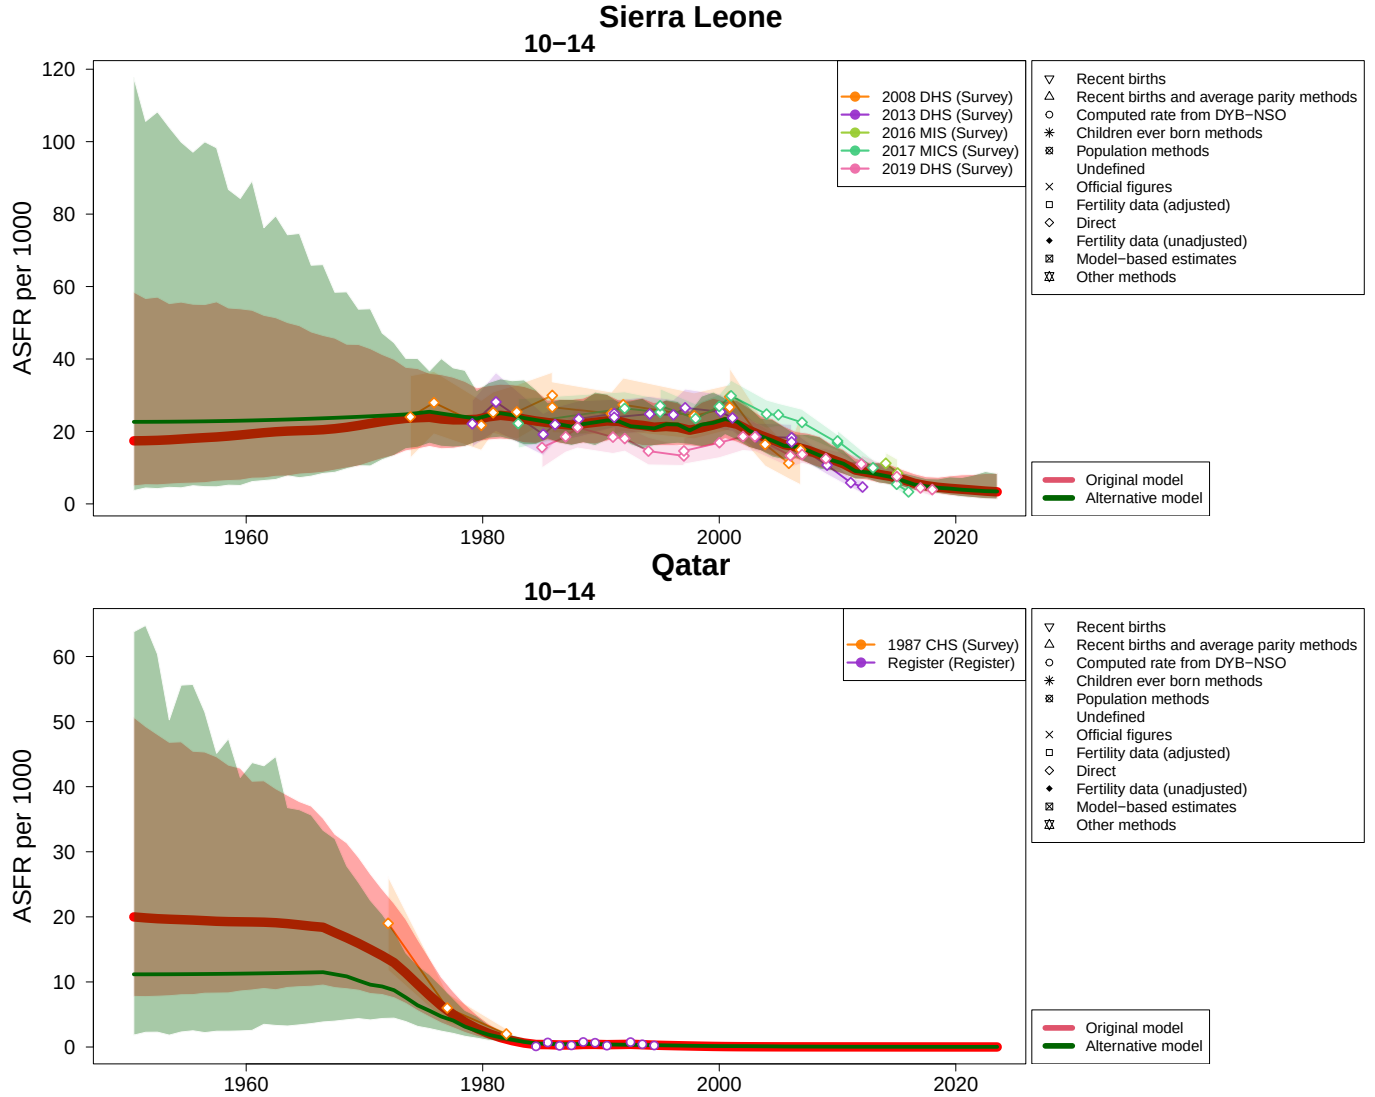

Figure 8: ASFR 10–14 model fit comparison during 1950–2023. Top: original model can provide narrower uncertainty bounds for country-periods without data. Bottom: original model provides more realistic backward projections in countries known to have high teenage fertility rate. Red curves and shades: median estimates and 95% uncertainty intervals from the original model (Section 3.4). Green curves and shades: median estimates and 95% uncertainty intervals from the alternative model (the same model as for ASFR 15–19 without using ASFR pattern from the neighbouring age group as described in Section 3.3). Dots with connection lines: input data series differentiated by colors. Shades around the data series: sampling errors (for non-VR data) or stochastic errors (for VR data).

The countries/areas (reason ID(s) of causing the high CVs are in the brackets after each country/area name) are:

- $\overline{CV}_{a,c} \in [20, +\infty]$: Dem. People's Republic of Korea (i, iii);
- $\overline{CV}_{a,c} \in [2, 20]$: Bhutan (i); China (i, iii); Cyprus (ii, iii); Georgia (ii, iii); Kuwait (ii, iii); Libya (iii); Mayotte (i); Saudi Arabia (i); Solomon Islands (i); United Arab Emirates (ii, iii); Vanuatu (i); Western Sahara (i);
- $\overline{CV}_{a,c} \in [1.5, 2]$: China, Macao SAR (iii); Curaçao (ii); Malaysia (ii, iii); Qatar (ii, iii); Serbia (ii, iii); Tonga (ii, iii);
- $\overline{CV}_{a,c} \in [1, 1.5]$: Aruba (ii); Azerbaijan (iii); Bahamas (ii); Bosnia and Herzegovina (ii, iii); Cabo Verde (ii); Equatorial Guinea (i); French Polynesia (iv); Lebanon (iv); North Macedonia (iii); Republic of Korea (iii); Republic of Moldova (iii); Slovenia (iii); Tajikistan (iii); Turkmenistan (iii);

The ASFR 10–14 observations, model estimates and uncertainty intervals during 1950–2023, by country are in Figure 15. One may refer to Figure 15 for the detailed information for each identified country model results.

7 Sub-regional results

We used the annual rate of reduction (ARR) to measure the instantaneous reduction over a period of time. While ARR were similar for both periods 1990–2015 and 2015–2023 at the global level, the declines differed by sub-region for each period (Figure 11). The ARR for age group 10–14 were significant in all sub-regions of Sub-Saharan Africa in 1990–2015. Particularly, Western Africa had significant reductions in both periods, with ARR increasing from 4.20% [3.28; 5.11] in 1990–2015 to 6.84% [0.62; 11.88] in 2015–2023, showing an acceleration of the reduction. Overall, sub-regions in other parts of the world experienced larger, when significant, reductions compared to Sub-Saharan African sub-regions.

For age group 15–19, most sub-regions with ARR significantly different from zero had a faster decline in the most recent period 2015–2023, rather than in the earlier years (1990–2015). The only exception is Southern Asia, where countries like India and Bangladesh experienced high rates of reduction in the earlier period (8.01% [7.58; 8.65] and 3.17% [2.31; 3.19], respectively, between 1990 and 2015), but had no significant reductions since 2015. Since 2015, the highest rates of reduction were registered in the regions with low adolescent birth rates, with Eastern Asia, all European sub-regions, Northern America, Australia and New Zealand having an ARR larger than 5% over the period 2015–2023, suggesting that adolescent birth rates can continue to decline to very low levels. Additionally, South America experienced a steep increase in the rate of reduction from 1.17% [0.78; 1.58] in 1990–2015 to 4.31% [2.93; 5.73] in 2015–2023. In countries like Argentina and Uruguay, the ARR was not significant in the period 1990–2015 and then reached 10.89% [8.44; 13.62] and 9.50% [6.22; 12.81] in 2015–2023, respectively. In Chile, ARR increased from 2.38% [1.76; 2.77] in 1990–2015 to 22.80% [20.79; 24.10] in 2015–2023. The sub-regions in Sub-Saharan Africa, where adolescent fertility reaches the highest values, did experience either non-significant reductions (Eastern Africa, Middle Africa) or low reduction rates (Southern Africa, Western Africa) compared to other regions. Melanesia, Micronesia and Polynesia did not have significant reductions in 2015–2023, while they experienced a reduction of less than 2% in 1990–2015.

8 Country-level results

This section provides an overview of the national ASFR distribution and spread relative to their regional ASFR and global ASFR for age groups 10–14 and 15–19. The interpretation of country-level outlying estimates should be taken with caution, because they suffer from lower data availability for the extreme cases.

The fertility rates for girls aged 10–14 and 15–19 varied substantially across countries in 2023, even after significant fertility declines globally and in all regions (Figure 12 and Figure 13). In Sub-Saharan Africa, the region with the highest fertility among girls under 15, four countries (Equatorial Guinea, Mauritania, Angola, and South Sudan) have estimated fertility rates of more than 10 births per 1,000 girls under 15 in 2023. In Eastern and South-Eastern Asia, Lao People's Democratic Republic exceeded 3.0 [0.9; 10.5] births per 1,000, despite lower regional rates overall. In Europe, Northern America, Australia, and New Zealand, where fertility rates for this age group are generally lowest, Bulgaria and Romania reported over 1 birth per 1,000 girls under 15, based on the complete data from the

Age 10–14

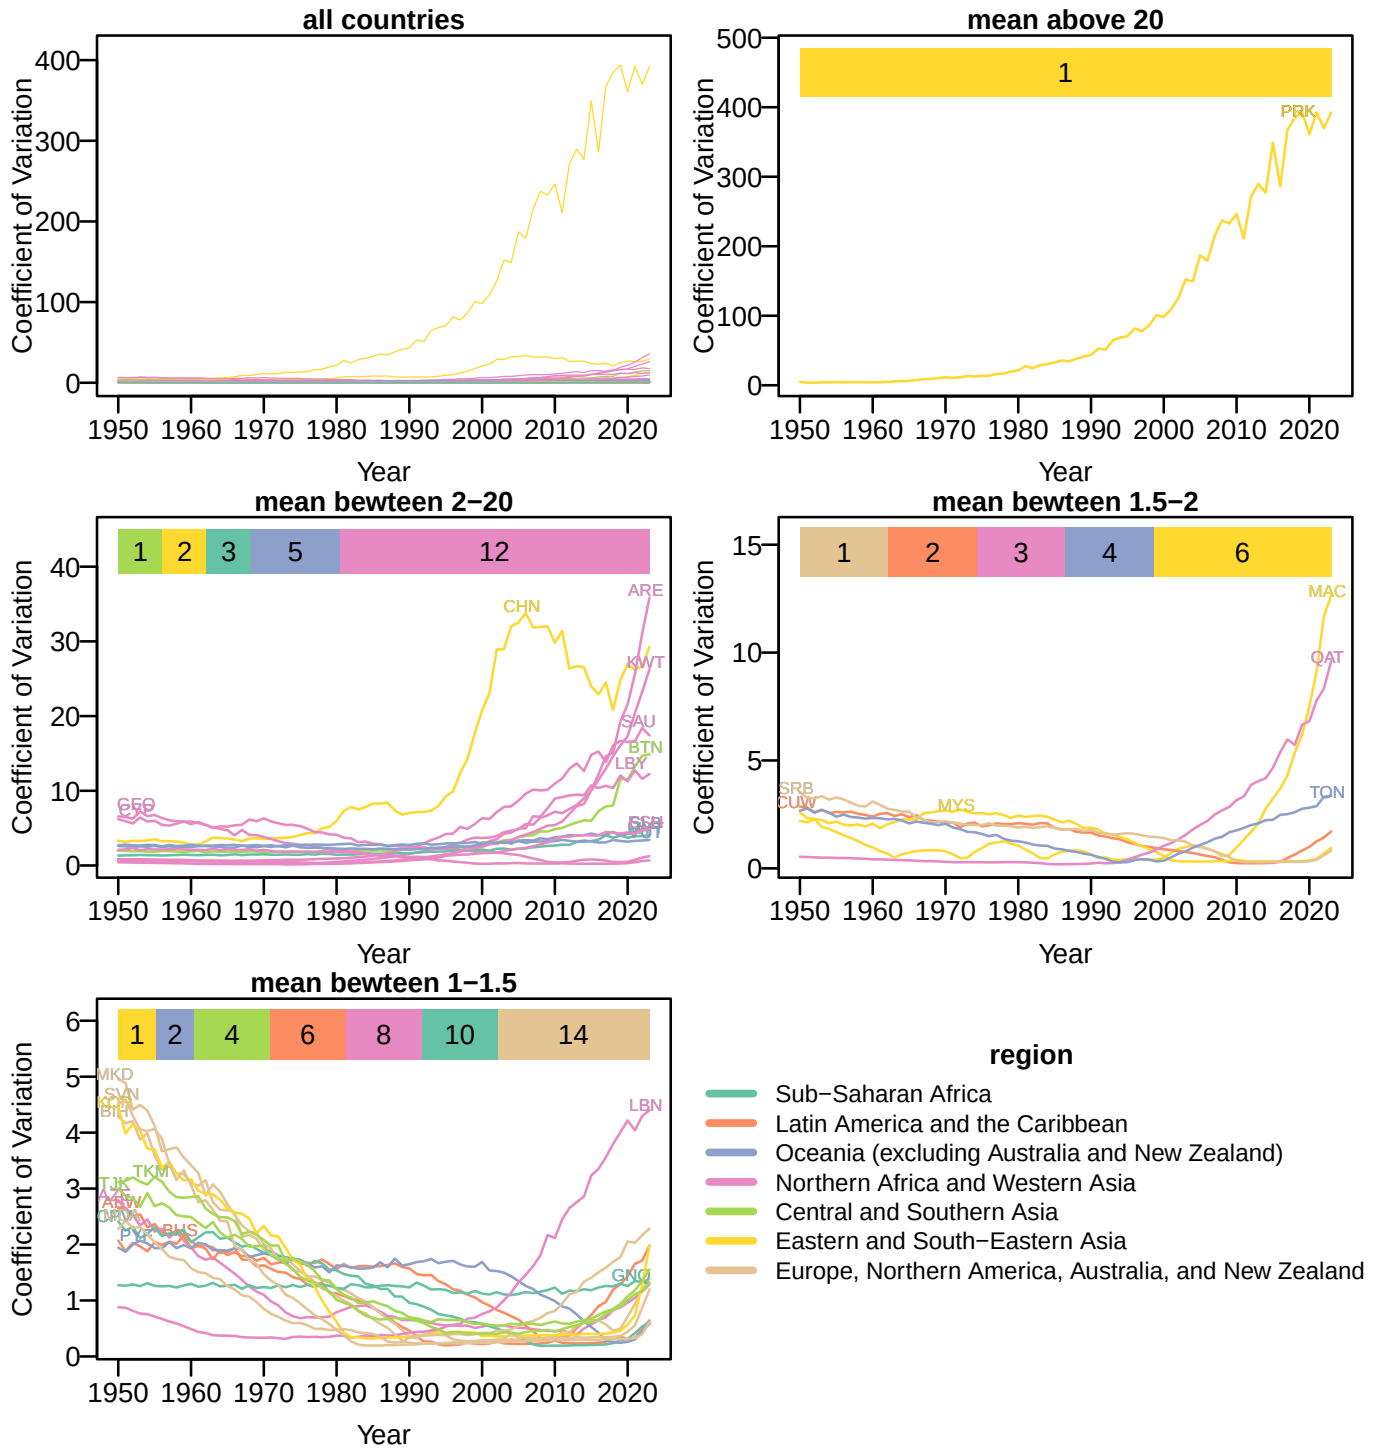

Figure 9: **Coefficient of variance (CV) for ASFR 10–14 model results, by country during 1950–2023.** Top left: CV by country over time for all countries. The remaining subfigures shows CV over time from countries with mean CV (average over time for each country) within intervals $[20, +\infty]$, $[2, 20]$, $[1.5, 2]$, and $[1, 1.5]$. Country time series are colored by region. The bar on top of each subfigure shows number of countries by region with mean CV falling into a certain interval. Country ISOs are listed next to each time series. Interval $[20, +\infty]$: PRK–Dem. People’s Republic of Korea. Interval $[2, 20]$: BTN–Bhutan; CHN–China; CYP–Cyprus; GEO–Georgia; KWT–Kuwait; LBY–Libya; MYT–Mayotte; SAU–Saudi Arabia; SLB–Solomon Islands; ARE–United Arab Emirates; VUT–Vanuatu; ESH–Western Sahara. Interval $[1.5, 2]$: MAC–China, Macao SAR; CUW–Curaçao; MYS–Malaysia; QAT–Qatar; SRB–Serbia; TON–Tonga. Interval $[1, 1.5]$: ABW–Aruba; AZE–Azerbaijan; BHS–Bahamas; BIH–Bosnia and Herzegovina; CPV–Cabo Verde; GNQ–Equatorial Guinea; PYF–French Polynesia; LBN–Lebanon; MKD–North Macedonia; KOR–Republic of Korea; MDA–Republic of Moldova; SVN–Slovenia; TJK–Tajikistan; TKM–Turkmenistan.

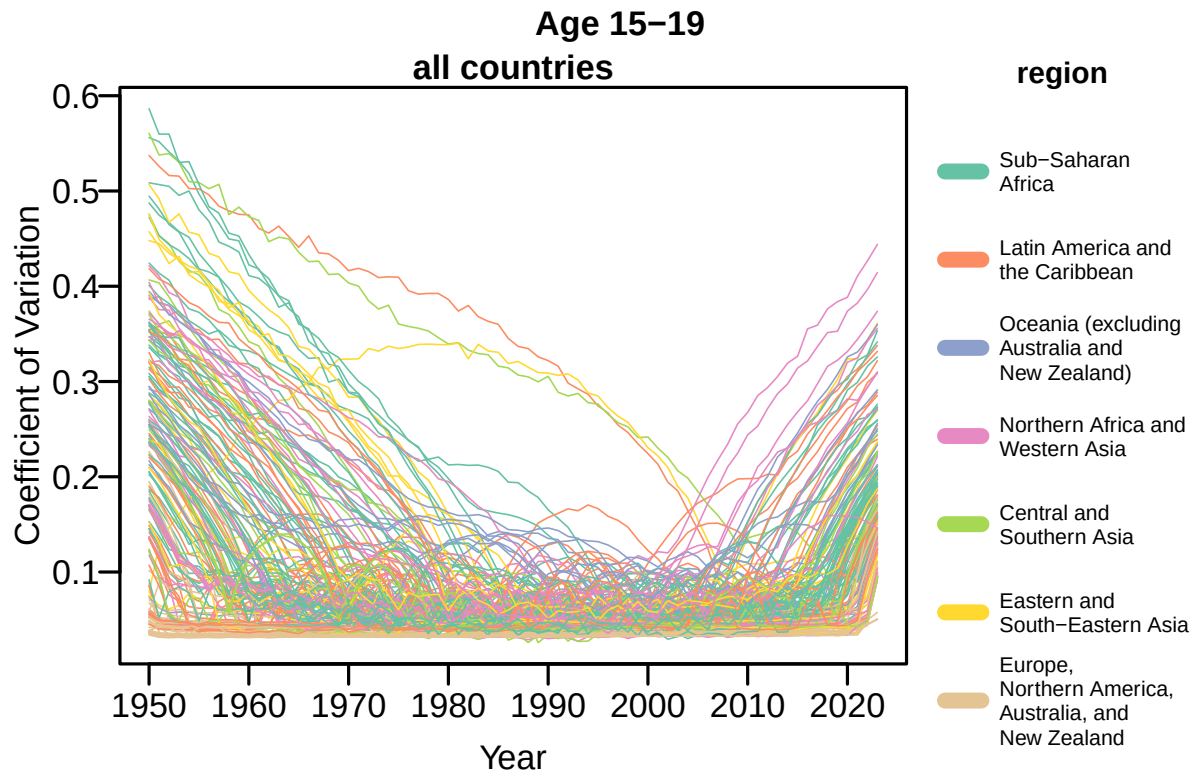

Figure 10: **Coefficient of variance for ASFR 15–19 model results, by country during 1950–2023.** Country time series are colored by region.

vital registration in the two countries. The national ASFR for the age group 15–19 follows a similar pattern as the age group 10–14, whereas the highest national fertility rates worldwide are concentrated in Sub-Saharan Africa and Latin America and the Caribbean, the variability within each region is less than that of the 10–14 age group. Only five countries are identified as outliers compared to other national fertility rates within a region. The fertility rate for ages 15–19 in the Lao People’s Democratic Republic is more than five times the regional level at 81.7 [59.9; 110.0] births per 1,000.

9 Comparison of the results with GBD 2021 estimates

Figure 14 illustrates the absolute and percentage differences between the estimates compiled for WPP 2024 Revision and the ones published by the Institute for Health Metrics and Evaluation (IHME) in the Global Burden of Disease Study 2021 [24]. Here, the absolute difference is computed as GBD estimate minus the Bayesian estimates (i.e. the absolute difference can be negative).

In 1990, GBD fertility estimates for age group 10–14 are lower than WPP in 78% of countries, with the largest absolute and relative differences observed in Sub-Saharan Africa. WPP estimates show a sharp decline after 1990, with rates falling below 1 child per 1,000 girls aged 10–14 in more than half of the countries, leading to smaller absolute differences in 2021.

Country-specific examples further illustrate these discrepancies (Table 13). In Liberia, WPP estimated that fertility had declined from 16.5 children per 1,000 girls aged 10–14 in 1990 to 4.7 in 2021. These estimates were informed by full birth history series coming from DHS and MICS surveys carried out between 2007 and 2022. In contrast, GBD estimated a decline from 1.8 children per 1,000 girls in 1990 (-88.9% compared to WPP) to 1.12 in 2021 (-75.1%), showing the crucial importance of data from birth histories for age group 10–14. Similarly, in Bangladesh, WPP estimated that fertility in this age group fell from 18.7 children per 1,000 girls in 1990 to 1.9 in 2021. GBD, however, estimated a decline from 2.1 to 1.1, leading to differences of -16.6% in 1990 and -40% in 2021 compared to WPP.

For girls aged 15–19, absolute differences between WPP and GBD estimates are larger than for girls aged 10–14,

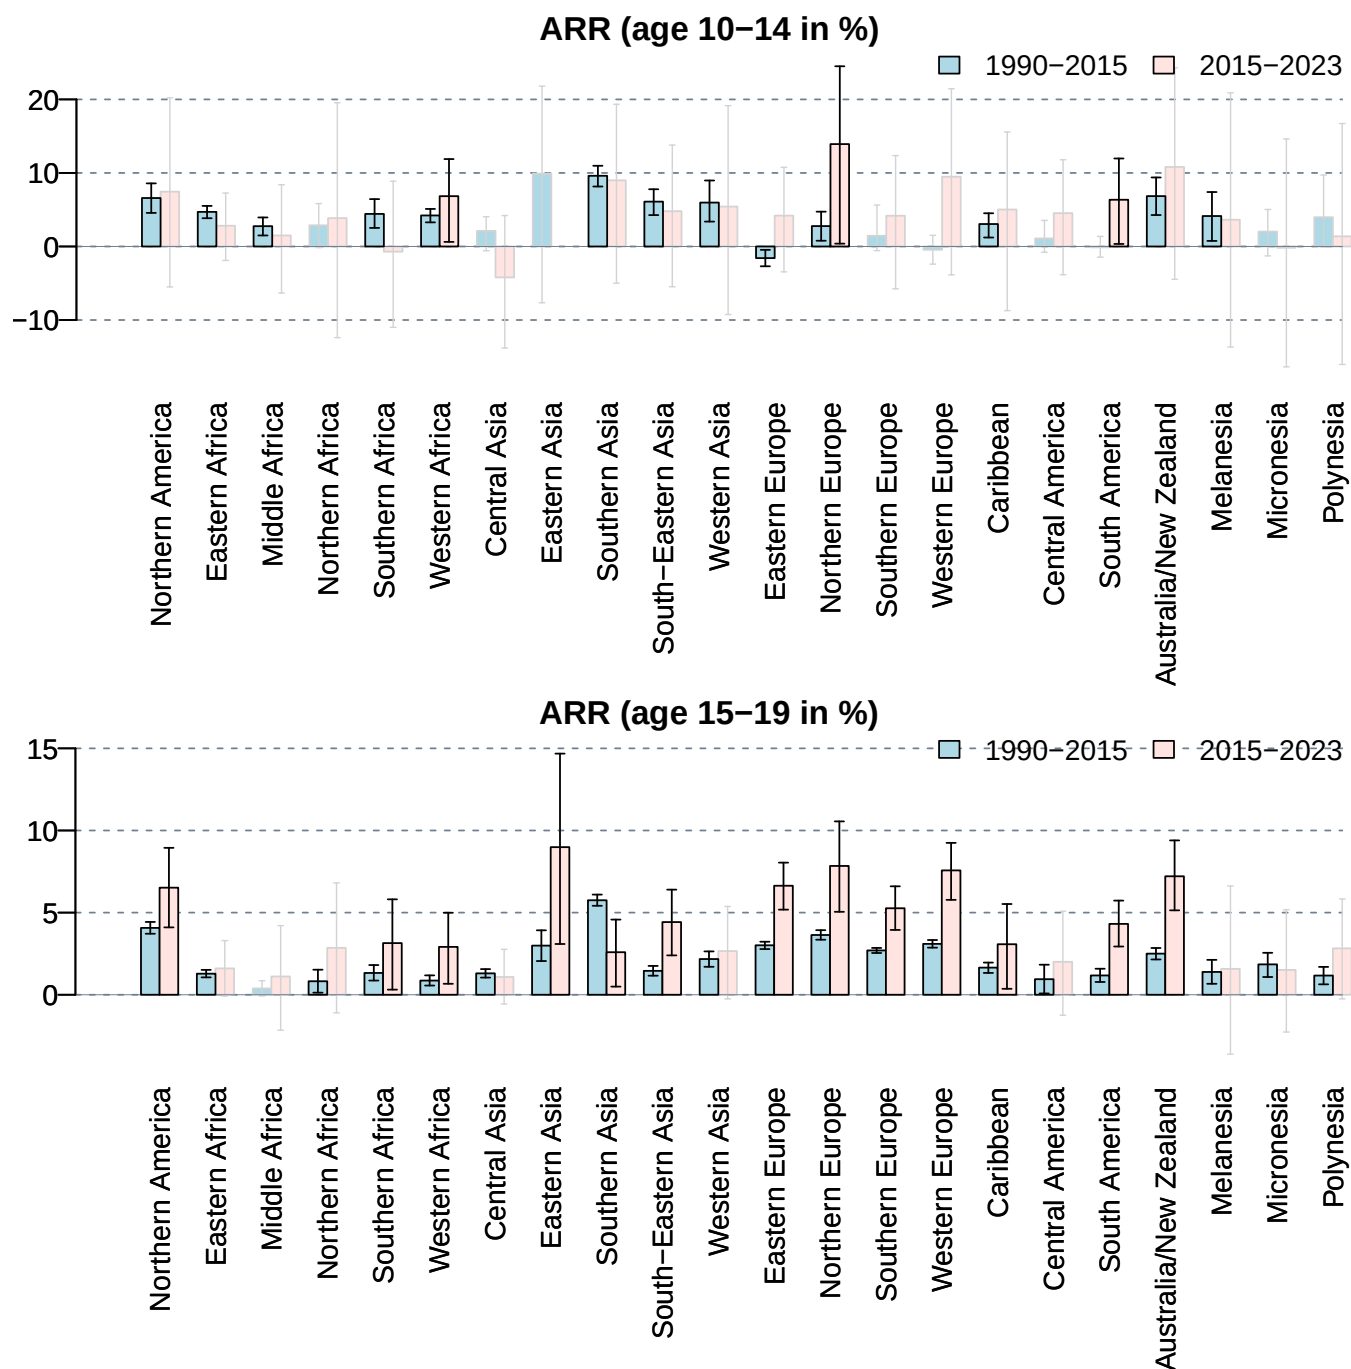

Figure 11: **ARR by mothers aged 10–14 (top) and 15–19 (bottom), in 22 sub-regions.** ARR is significantly different from zero are shown in black bars; otherwise, they are in grey. We do not report ARR if the age-specific fertility rates in both years are below 0.01 per 1,000. ARR: annual rates of reduction.

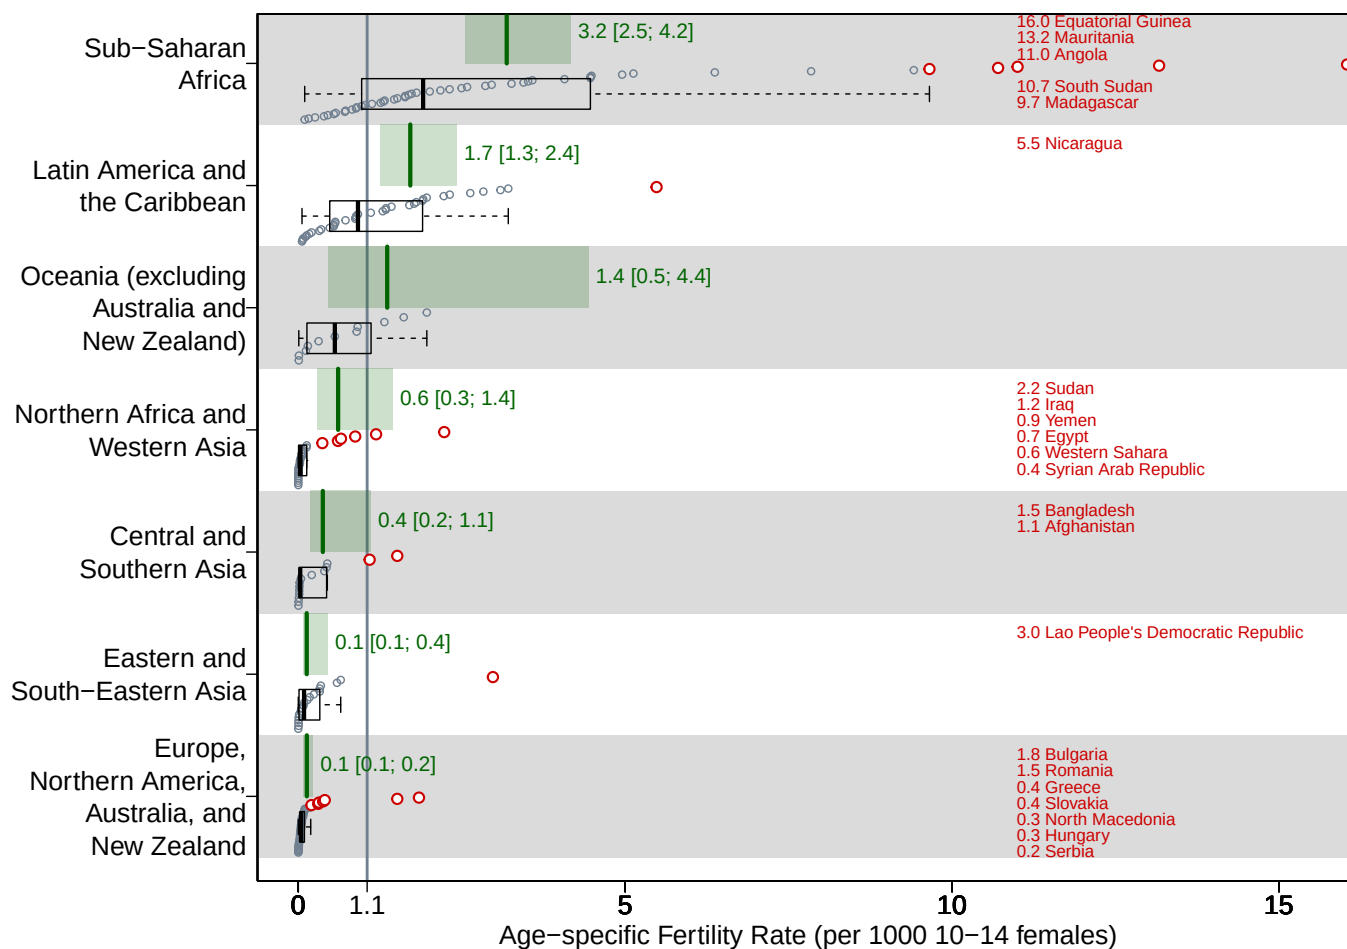

Figure 12: **ASFR aged 10–14 in 2023 on global, regional, and national levels.** Global ASFR: grey vertical line. Regional ASFR: median estimates are in dark green line segments with 95% uncertainty intervals as shaded areas and printed values in green. Box plots summarize the distributions of national ASFR within each region. National ASFRs are shown (dots), with those outside the range of [25th percentile–1.5IQR; 75th percentile+1.5IQR] highlighted in red. The countries with outlying national ASFR are listed in the legend with the median estimates reported (ordered by median estimate).

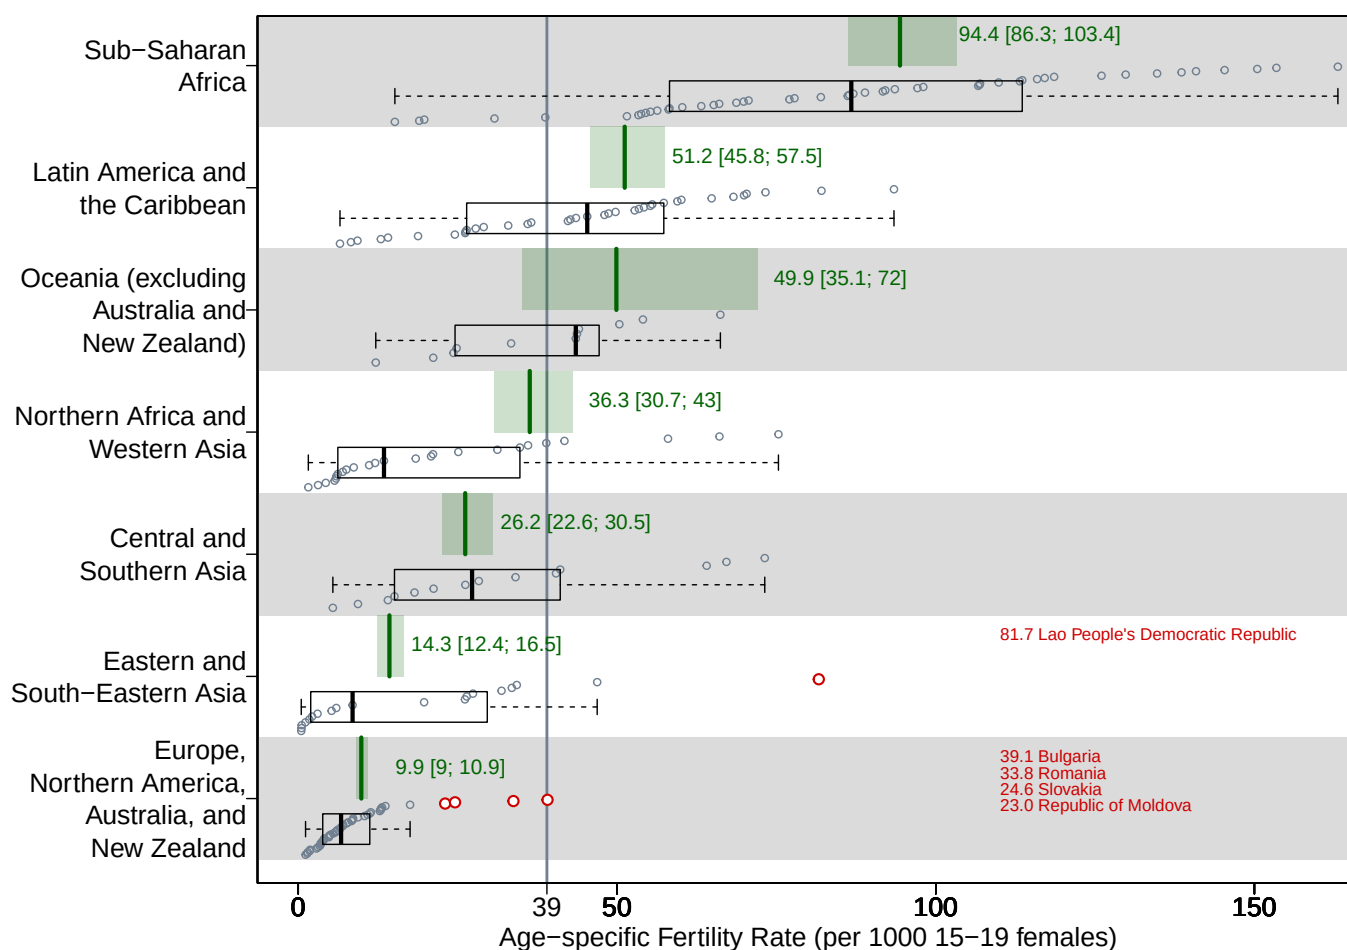

Figure 13: **ASFR aged 15–19 in 2023 on global, regional, and national levels.** Global ASFR: grey vertical line. Regional ASFR: median estimates are in dark green line segments with 95% uncertainty intervals as shaded areas and printed values in green. Box plots summarize the distributions of national ASFR within each region. National ASFRs are shown (dots), with those outside the range of [25th percentile–1.5IQR; 75th percentile+1.5IQR] highlighted in red. The countries with outlying national ASFR are listed in the legend with the median estimates reported (ordered by median estimate).

which aligns with generally higher fertility levels in this age group. However, percentage differences are narrower. In 1990, the largest discrepancies were concentrated in Central and Southern Asia. By 2021, the largest absolute differences were found in Sub-Saharan Africa, and the largest relative differences in Northern Africa and Western Asia, a result of WPP estimates being based on more recent data.

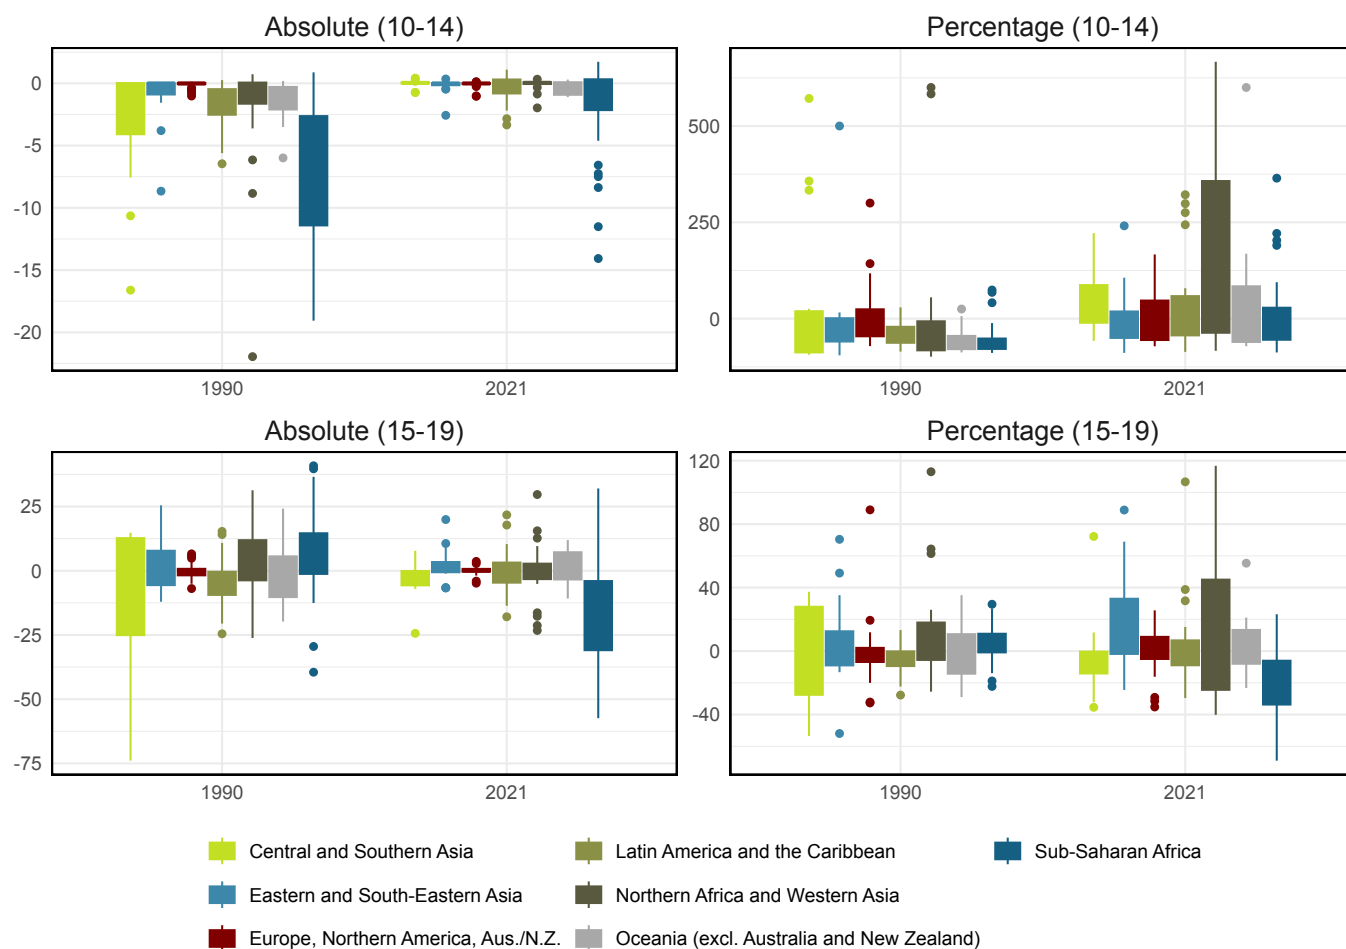

Figure 14: **Distribution of regional absolute and percentage differences between the WPP 2024[1] and the GBD 2021 estimates, for years 1990 and 2021.** Top row: results for ages 10–14. Bottom row: results for ages 15–19. Left column: absolute differences between the WPP 2024 and the GBD 2021 estimates. Right column: percentage differences between the WPP 2024 and the GBD 2021 estimates. Results from different regions are in different colors.

10 GATHER Compliance

Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER) are reported in Table 11.

Table 11: **Checklist of information that should be included in new reports of global health estimates.** M: main manuscript. A: Appendix. Section titles after “M” are stated for the main manuscript. Page numbers after “A” are shown for the appendix.

Item #	Checklist item	Reported on page # or section #
Objectives and funding		
1	Define the indicator(s), populations (including age, sex, and geographic entities), and time period(s) for which estimates were made.	M-Introduction, A1–5
2	List the funding sources for the work.	M-Abstract
Data inputs		
<i>For all data inputs from multiple sources that are synthesized as part of the study:</i>		
3	Describe how the data were identified and how the data were accessed.	M-Database construction, A1–5
4	Specify the inclusion and exclusion criteria. Identify all ad-hoc exclusions.	M-Database construction, A5–7
5	Provide information on all included data sources and their main characteristics. For each data source used, report reference information or contact name/institution, the population represented, data collection method, year(s) of data collection, sex and age range, diagnostic criteria or measurement method, and sample size, as relevant.	A1–5 & A55–111
6	Identify and describe any categories of input data that have potentially important biases (e.g., based on characteristics listed in item 5).	A5–7
<i>For data inputs that contribute to the analysis but were not synthesized as part of the study:</i>		
7	Describe and give sources for any other data inputs.	M-Database construction, A1–6
<i>For all data inputs:</i>		
8	Provide all data inputs in a file format from which data can be efficiently extracted (e.g., a spreadsheet rather than a PDF), including all relevant meta-data listed in item 5. For any data inputs that cannot be shared because of ethical or legal reasons, such as third-party ownership, provide a contact name or the name of the institution that retains the right to the data.	M-Database construction
Data analysis		
9	Provide a conceptual overview of the data analysis method. A diagram may be helpful.	M-Database construction, A8
10	Provide a detailed description of all analysis steps, including mathematical formulae. This description should cover, as relevant, data cleaning, data pre-processing, data adjustments and weighting of data sources, and mathematical or statistical model(s).	M-Statistical analysis, A5–17
11	Describe how candidate models were evaluated and how the final model(s) were selected.	M-Statistical analysis, A17
12	Provide the results of an evaluation of model performance, if done, as well as the results of any relevant sensitivity analysis.	A17–21

Continued on next page

Table 11 – continued from previous page

Item #	Checklist item	Reported on page # or section #
13	Describe methods for calculating the uncertainty of the estimates. State which sources of uncertainty were, and were not, accounted for in the uncertainty analysis.	A7–17
14	State how analytic or statistical source code used to generate estimates can be accessed.	M-Statistical analysis
Results and Discussion		
15	Provide published estimates in a file format from which data can be efficiently extracted.	A33–55 & 111
16	Report a quantitative measure of the uncertainty of the estimates (e.g., uncertainty intervals).	A21–23
17	Interpret results in light of existing evidence. If updating a previous set of estimates, describe the reasons for changes in estimates.	M-Results
18	Discuss limitations of the estimates. Include a discussion of any modelling assumptions or data limitations that affect the interpretation of the estimates.	M-Discussion

11 Supplementary tables

- Table 12: Classification of countries/areas by SGD region and subregion (page 31–33).
- Table 13: Estimates and 95% uncertainty intervals for ASFR 10–14 in 1990, 2015, and 2023, for the world, SDG regions, subregions, and all countries (page 33–39).
- Table 14: Estimates and 95% uncertainty intervals for ASFR 15–19 in 1990, 2015, and 2023, for the world, SDG regions, subregions, and all countries (page 39–45).
- Table 15: Estimates and uncertainty intervals for births (in thousands) by mothers aged 10–14 and the percentage of births in each location among all births of 10–14 for 1990, 2015, and 2023 for the world, SDG regions, subregions, and all countries (page 45–50).
- Table 16: Estimates and uncertainty intervals for births (in thousands) by mothers aged 15–19 and the percentage of births in each location among all births of 15–19 for 1990, 2015, and 2023 for the world, SDG regions, subregions, and all countries (page 50–55).
- Table 17: Age-specific fertility rate data sources for age group 10–14, by country (page 55–75).
- Table 18: Age-specific fertility rate data sources for age group 15–19, by country (page 75–111).

Table 12: Classification of countries/areas by SGD region and subregion. Countries are in alphabetical order in each subregion. Numbers in brackets after each region and subregion name indicate the number of countries from each (sub)region. Only countries/areas with population size above 90,000 by mid-2024 are shown.

SDG Region	Subregion	Country/Area
Sub-Saharan Africa [50]	Middle Africa [9]	Angola; Cameroon; Central African Republic; Chad; Republic of the Congo; Democratic Republic of the Congo; Equatorial Guinea; Gabon; Sao Tome and Principe
	Western Africa [16]	Benin; Burkina Faso; Cabo Verde; Côte d’Ivoire; Gambia; Ghana; Guinea; Guinea-Bissau; Liberia; Mali; Mauritania; Niger; Nigeria; Senegal; Sierra Leone; Togo
	Southern Africa [5]	Botswana; Eswatini; Lesotho; Namibia; South Africa
	Eastern Africa [20]	Burundi; Comoros; Djibouti; Eritrea; Ethiopia; Kenya; Madagascar; Malawi; Mauritius; Mayotte; Mozambique; Réunion; Rwanda; Seychelles; Somalia; South Sudan; Uganda; United Republic of Tanzania; Zambia; Zimbabwe
Latin America and the Caribbean [37]	Caribbean [16]	Antigua and Barbuda; Aruba; Bahamas; Barbados; Cuba; Curaçao; Dominican Republic; Grenada; Guadeloupe; Haiti; Jamaica; Martinique; Puerto Rico; Saint Lucia; Saint Vincent and the Grenadines; Trinidad and Tobago
	South America [13]	Argentina; Bolivia (Plurinational State of); Brazil; Chile; Colombia; Ecuador; French Guiana; Guyana; Paraguay; Peru; Suriname; Uruguay; Venezuela (Bolivarian Republic of)
	Central America [8]	Belize; Costa Rica; El Salvador; Guatemala; Honduras; Mexico; Nicaragua; Panama
Oceania (excluding Australia and New Zealand) [11]	Polynesia [3]	French Polynesia; Samoa; Tonga
	Melanesia [5]	Fiji; New Caledonia; Papua New Guinea; Solomon Islands; Vanuatu
	Micronesia [3]	Guam; Kiribati; Micronesia (Fed. States of)

Table 12 – continued from previous page

SDG Region	Subregion	Country/Area
Northern Africa and Western Asia [25]	Northern Africa [7]	Algeria; Egypt; Libya; Morocco; Sudan; Tunisia; Western Sahara
	Western Asia [18]	Armenia; Azerbaijan; Bahrain; Cyprus; Georgia; Iraq; Israel; Jordan; Kuwait; Lebanon; Oman; Qatar; Saudi Arabia; State of Palestine; Syrian Arab Republic; Türkiye; United Arab Emirates; Yemen
Central and Southern Asia [14]	Southern Asia [9]	Afghanistan; Bangladesh; Bhutan; India; Iran (Islamic Republic of); Maldives; Nepal; Pakistan; Sri Lanka
	Central Asia [5]	Kazakhstan; Kyrgyz Republic; Tajikistan; Turkmenistan; Uzbekistan
Eastern and South-Eastern Asia [19]	South-Eastern Asia [11]	Brunei Darussalam; Cambodia; Indonesia; Lao People's Democratic Republic; Malaysia; Myanmar; Philippines; Singapore; Thailand; Timor-Leste; Viet Nam
	Eastern Asia [8]	China; China, Hong Kong SAR; Macao, SAR of China; China, Taiwan Province of China; Dem. People's Republic of Korea; Japan; Mongolia; Republic of Korea
Europe, Northern America, Australia, and New Zealand [45]	Southern Europe [13]	Albania; Bosnia and Herzegovina; Croatia; Greece; Italy; Kosovo (under UNSC res. 1244); Malta; Montenegro; North Macedonia; Portugal; Serbia; Slovenia; Spain
	Australia/New Zealand [2]	Australia; New Zealand
	Western Europe [7]	Austria; Belgium; France; Germany; Luxembourg; Netherlands; Switzerland
	Eastern Europe [10]	Belarus; Bulgaria; Czechia; Hungary; Poland; Republic of Moldova; Romania; Russian Federation; Slovakia; Ukraine
	Northern America [2]	Canada; United States of America
	Northern Europe [11]	Denmark; Estonia; Finland; Iceland; Ireland; Jersey; Latvia; Lithuania; Norway; Sweden; United Kingdom

Table 13: Estimates and 95% uncertainty intervals for ASFR 10–14 in 1990, 2015, and 2023, the total changes between 1990–2015, between 2015–2013, and between 1990–2023, and the annual rate of reduction (ARR) between 1990–2015, between 2015–2013, and between 1990–2023, for the world, seven SDG regions, 22 sub-regions, and 201 countries*. †: Change or ARR is significantly different from zero. *We report results from countries/areas with more than 90,000 population size by mid-2024.

Age-specific fertility rate 10–14										
Location Name	Location Type	Estimate (per 1,000)			Total Change (per 1,000)			Annual Rate of Reduction (per 100)		
		1990	2015	2023	1990–2015	2015–2023	1990–2023	1990–2015	2015–2023	1990–2023

†: Change is significantly different from zero.

Total Change (Year 1–Year 2): ASFR (Year 2) - ASFR (Year 1).

Annual Rate of Reduction (Year 1–Year 2): $\log(\text{ASFR}_{\text{Year 2}}/\text{ASFR}_{\text{Year 1}})/(\text{Year 1} - \text{Year 2})$, where Year 1 is smaller than Year 2.

†: Change is significantly different from zero.

Total Change (Year 1–Year 2): ASFR (Year 2) - ASFR (Year 1).

Annual Rate of Reduction (Year 1–Year 2): $\log(\text{ASFR}_{\text{Year 2}}/\text{ASFR}_{\text{Year 1}})/(\text{Year 1} - \text{Year 2})$, where Year 1 is smaller than Year 2.

†: Change is significantly different from zero.

Total Change (Year 1–Year 2): ASFR (Year 2) - ASFR (Year 1).

Annual Rate of Reduction (Year 1–Year 2): $\log(\text{ASFR}_{\text{Year 2}}/\text{ASFR}_{\text{Year 1}})/(\text{Year 1} - \text{Year 2})$, where Year 1 is smaller than Year 2.

†: Change is significantly different from zero.

Total Change (Year 1–Year 2): ASFR (Year 2) – ASFR (Year 1).

Annual Rate of Reduction (Year 1–Year 2): $\log(\text{ASFR}_{\text{Year 2}}/\text{ASFR}_{\text{Year 1}})/(\text{Year 1} - \text{Year 2})$, where Year 1 is smaller than Year 2.

†: Change is significantly different from zero.

Total Change (Year 1–Year 2): ASFR (Year 2) - ASFR (Year 1).

Annual Rate of Reduction (Year 1–Year 2): $\log(\text{ASFR}_{\text{Year 2}}/\text{ASFR}_{\text{Year 1}})/(\text{Year 1} - \text{Year 2})$, where Year 1 is smaller than Year 2.

†: Change is significantly different from zero.

Total Change (Year 1–Year 2): ASFR (Year 2) - ASFR (Year 1).

Annual Rate of Reduction (Year 1–Year 2): $\log(\text{ASFR}_{\text{Year 2}}/\text{ASFR}_{\text{Year 1}})/(\text{Year 1} - \text{Year 2})$, where Year 1 is smaller than Year 2.

†: Change is significantly different from zero.

Total Change (Year 1–Year 2): ASFR (Year 2) - ASFR (Year 1).

Annual Rate of Reduction (Year 1–Year 2): $\log(\text{ASFR}_{\text{Year 2}}/\text{ASFR}_{\text{Year 1}})/(\text{Year 1} - \text{Year 2})$, where Year 1 is smaller than Year 2.

†: Change is significantly different from zero.

Total Change (Year 1–Year 2): ASFR (Year 2) - ASFR (Year 1).

Annual Rate of Reduction (Year 1–Year 2): $\log(\text{ASFR}_{\text{Year 2}}/\text{ASFR}_{\text{Year 1}})/(\text{Year 1} - \text{Year 2})$, where Year 1 is smaller than Year 2.

†: Change is significantly different from zero.

Total Change (Year 1–Year 2): ASFR (Year 2) - ASFR (Year 1).

Annual Rate of Reduction (Year 1–Year 2): $\log(\text{ASFR}_{\text{Year 2}}/\text{ASFR}_{\text{Year 1}})/(\text{Year 1} - \text{Year 2})$, where Year 1 is smaller than Year 2.

Table 15: **Estimates and uncertainty intervals for births (in thousands) by mothers aged 10–14 and the percentage of births in each location among all births of 10–14 for 1990, 2015, and 2023 for the world, seven SDG regions, 22 sub-regions, and 201 countries/areas*.** *We report results from countries/areas with more than 90,000 population size by mid-2024. Percentages may not sum up to 1 due to rounding.

Location Name	Location Type	Age-specific births 10–14 Number (in thousands)			Proportion (in %)		
		1990	2015	2023	1990	2015	2023
World	World	1,150 [1,050; 1,340]	446 [407; 499]	347 [285; 454]	100	100	100

Table 16: **Estimates and uncertainty intervals for births (in thousands) by mothers aged 15–19 and the percentage of births in each location among all births of 15–19 for 1990, 2015, and 2023 for the world, seven SDG regions, 22 sub-regions, and 201 countries/areas*.** *We report results from countries/areas with more than 90,000 population size by mid-2024. Percentages may not sum up to 1 due to rounding.

Location Name	Location Type	Age-specific births 15–19 Number (in thousands)			Proportion (in %)

Table 17: **Age-specific fertility rate data sources for age group 10–14, by country.** For each country, the total number of observations and the most recent reference year are shown after the country name. For each country-specific data series, the number of observations and the most recent reference year within that series are shown before each data series name. The source type that each data series falls in is shown in parentheses after each data series name. Countries without data are shown in grey rows (if applicable). Only countries/areas with population size above 90,000 by mid-2024 are shown.

Table 18: **Age-specific fertility rate data sources for age group 15–19, by country.** For each country, the total number of observations and the most recent reference year are shown after the country name. For each country-specific data series, the number of observations and the most recent reference year within that series are shown before each data series name. The source type that each data series falls in is shown in parentheses after each data series name. Countries without data are shown in grey rows (if applicable). Only countries/areas with population size above 90,000 by mid-2024 are shown.

12 Supplementary figures

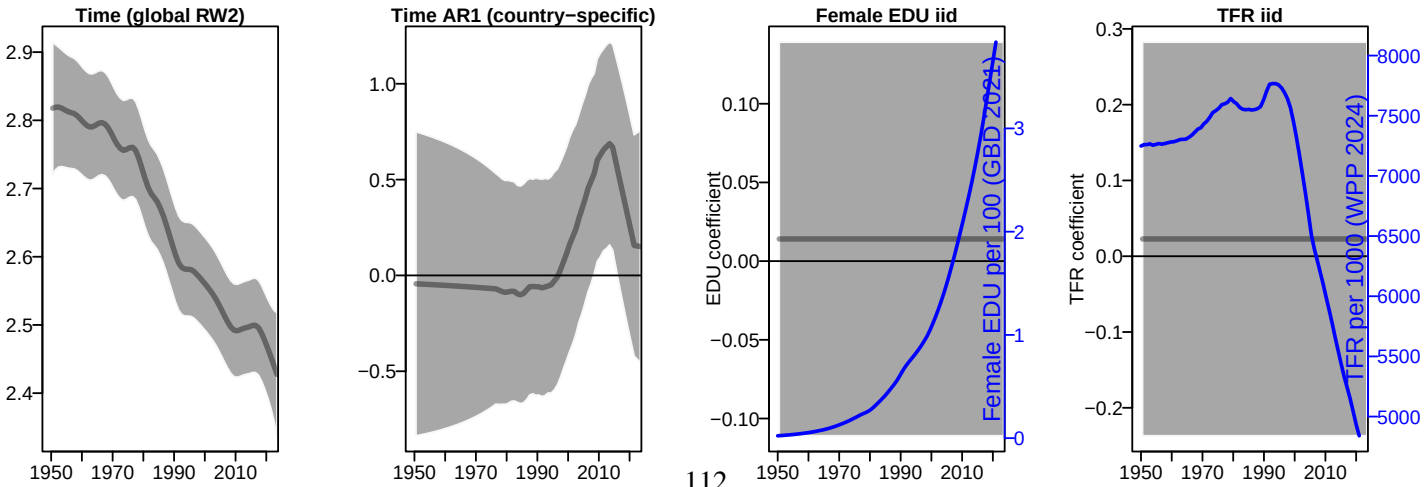

- Figure 15: ASFR 10–14 estimates and uncertainty intervals during 1950–2023, by country (page 111–313).
- Figure 16: ASFR 15–19 estimates and uncertainty intervals during 1950–2023, by country (page 313–515).

Figure 15: **ASFR 10–14 estimates and uncertainty intervals during 1950–2023, by country.** Red curves and shades: ASFR 10–14 median estimates and 95% uncertainty intervals. Black curves: GBD 2021 estimates. Dots with connection lines: input data series differentiated by colors. Shades around the data series: sampling errors (for non-VR data) or stochastic errors (for VR data). Bayesian model elements results are shown at the bottom of each page.

Bayesian model elements

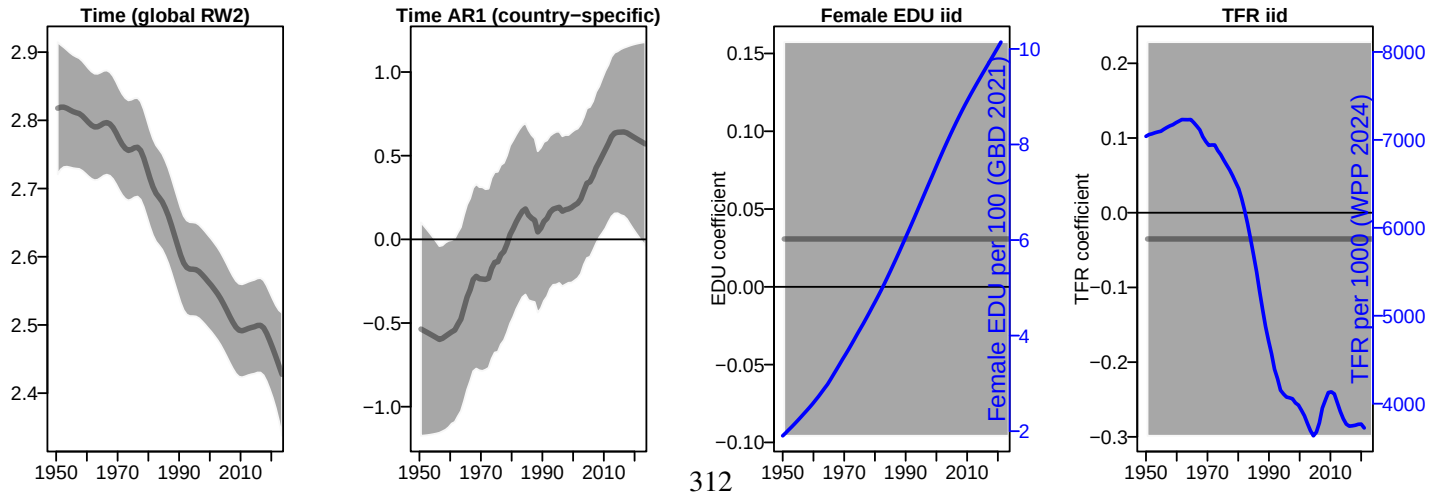

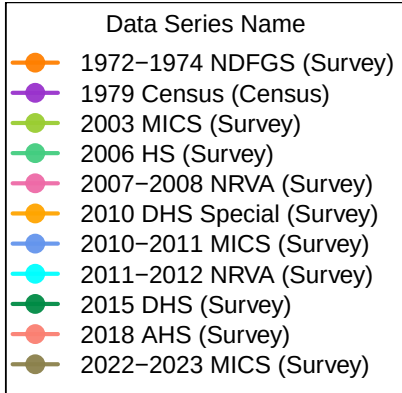

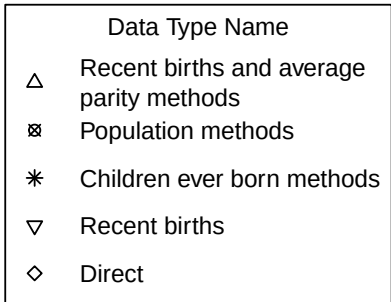

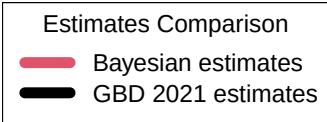

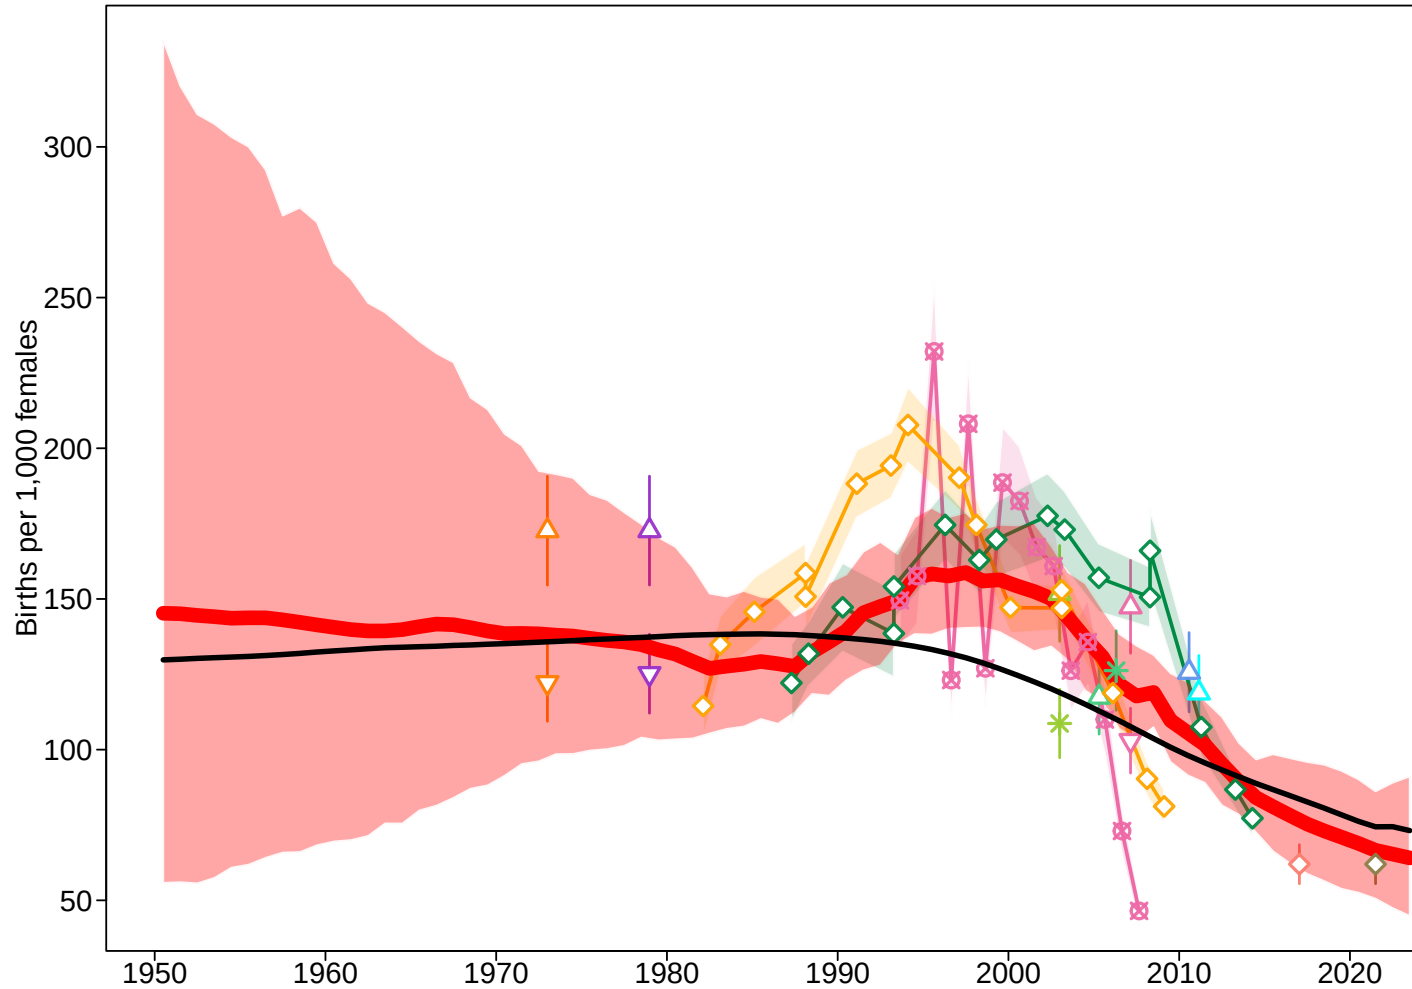

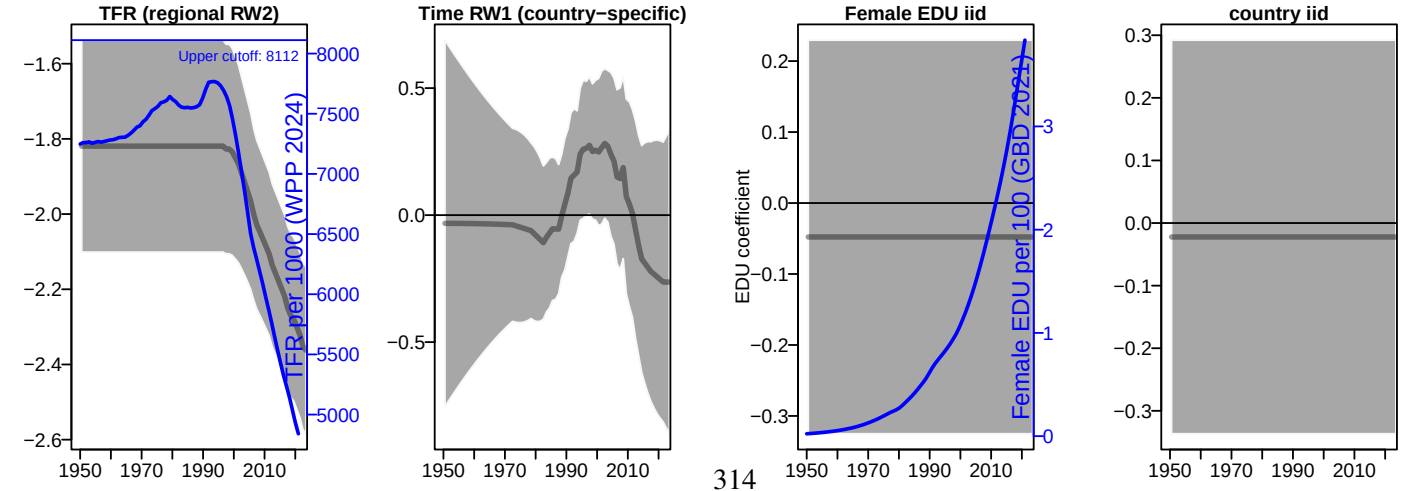

Figure 16: **ASFR 15–19 estimates and uncertainty intervals during 1950–2023, by country.** Red curves and shades: ASFR 15–19 median estimates and 95% uncertainty intervals. Black curves: GBD 2021 estimates. Dots with connection lines: input data series differentiated by colors. Shades around the data series: sampling errors (for non-VR data) or stochastic errors (for VR data). Bayesian model elements results are shown at the bottom of each page.

Bayesian model elements

United Republic of Tanzania (age group 15–19)

Estimates Comparison

- Bayesian estimates
- GBD 2021 estimates

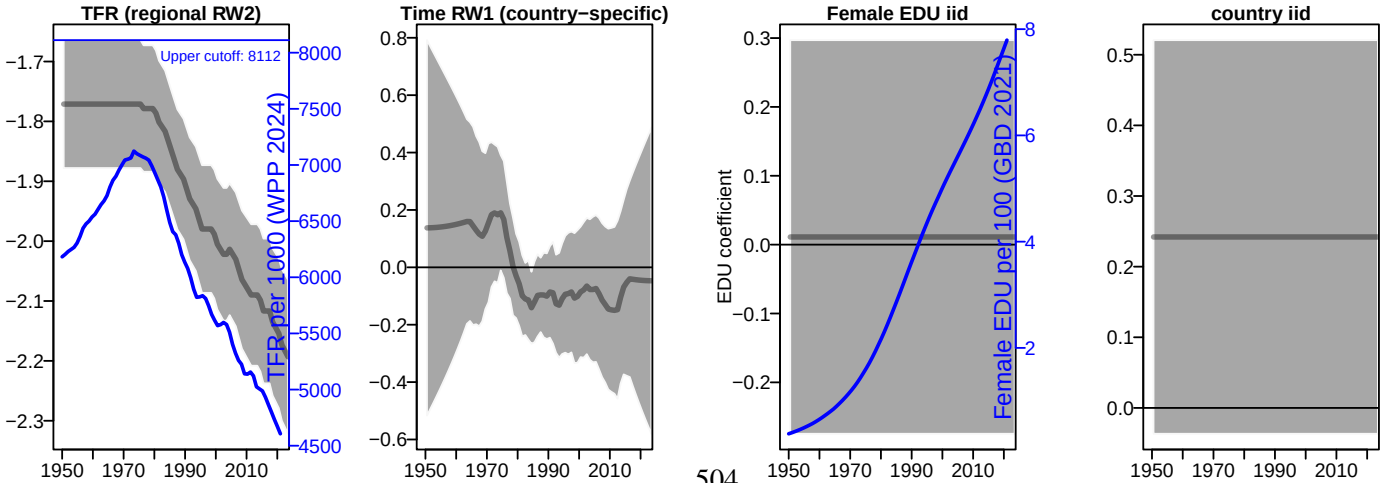

Data Type Name

- Recent births
- Recent births and average parity methods
- Direct
- Population methods
- Fertility data (adjusted)

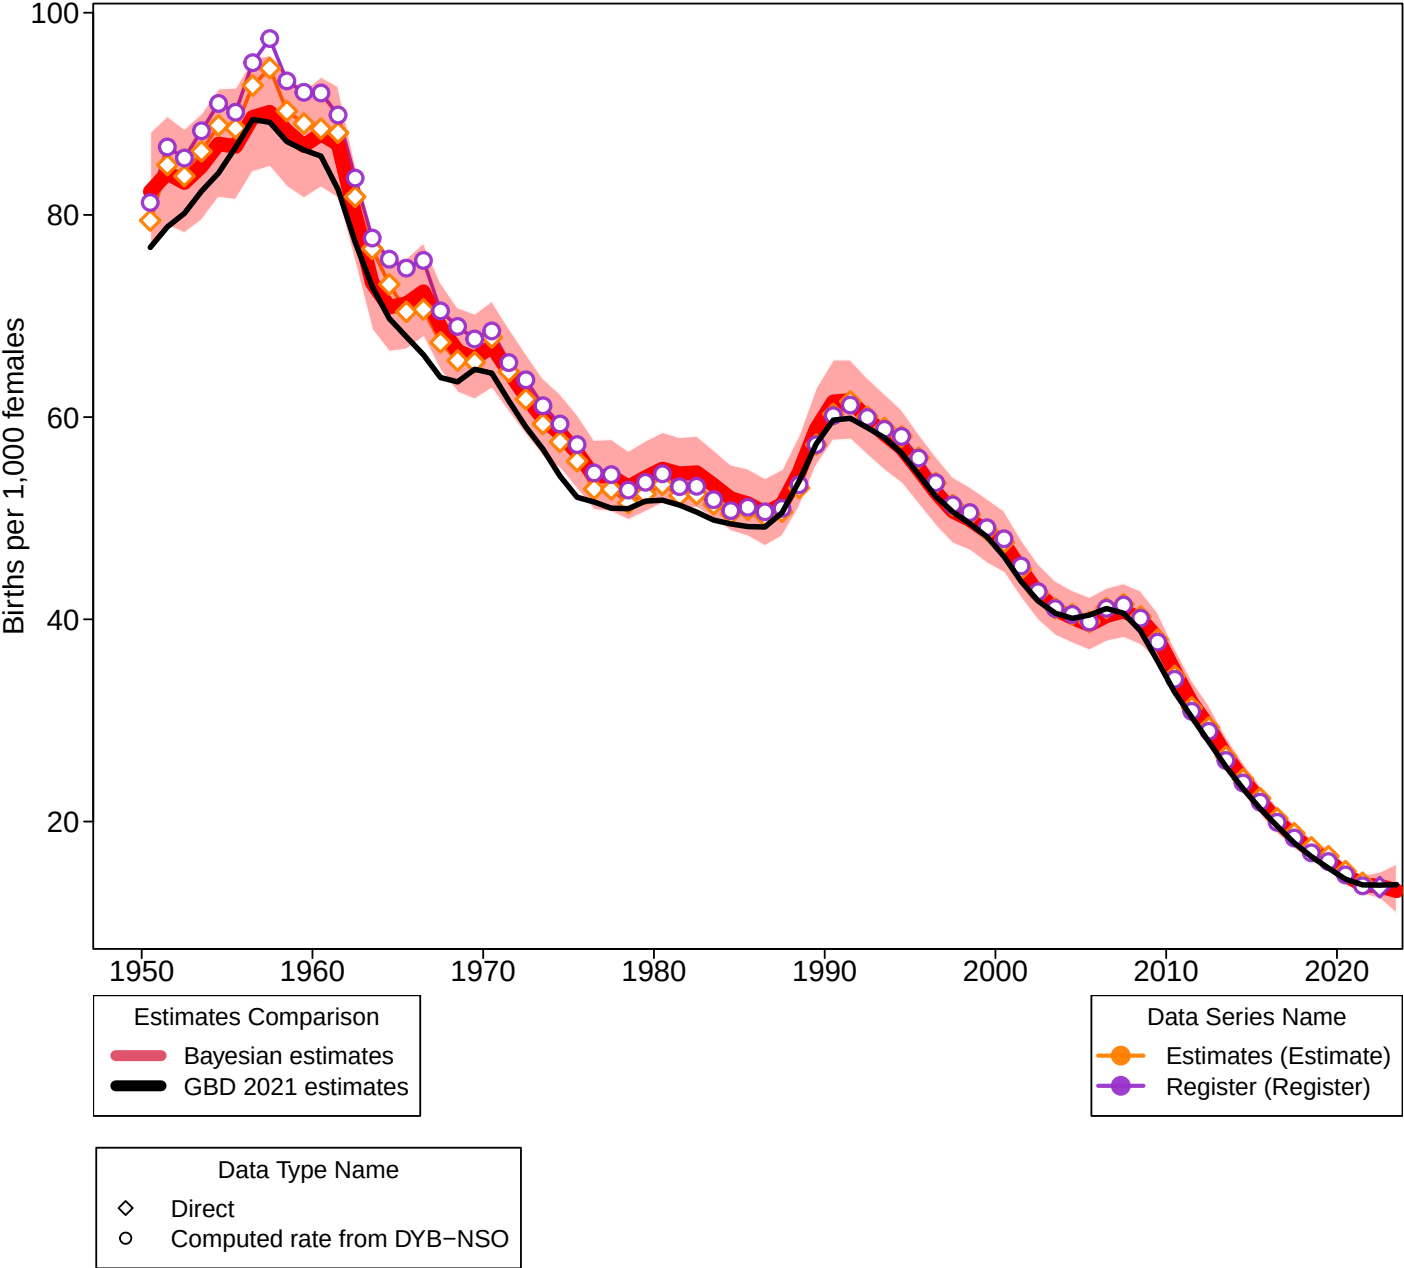

Data Series Name

- 1967 Census (Census)
- 1973 NDS (Survey)
- 1978 Census (Census)
- 1988 Census (Census)
- 1991–1992 DHS (Survey)
- 1994 KAP Survey (Survey)
- 1995 SUMVE In Depth Study (Survey)
- 1996 DHS (Survey)
- 1999 RCHS (Survey)
- 2002 Census (Census)
- 2004–2005 DHS (Survey)
- 2007–2008 AIS (Survey)
- 2010 DHS (Survey)
- 2011–2012 AIS (Survey)
- 2012 Census (Census)
- 2015–2016 DHS (Survey)
- 2017 MIS (Survey)
- Estimates (Estimate)
